Mr. Weir asked the President of the Local Government Board if he would state when public vaccinators discontinued the use of human lymph and for what reason its use was abandoned.—Mr. Long replied: The use of human lymph by public vaccinators was discontinued at the beginning of 1899 when the Vaccination Act of 1898 came into operation. The change was made in view of the recommendation of the Royal Commission on Vaccination.

"False Description in the Spirit Trade."

Mr. T. M. Healy a[illegible] Exchequer if he would state the total quanti[illegible] land during the year 1902 and how much [illegible] rectifying, and compounding purposes; [illegible] was used as whisky in Excise or Customs' warehouses in Leith; and, if so, what was the total quantity despatched thereto from distilleries in England; what were the materials from which English spirit was usually distilled; and if any beet molasses from abroad was used i[illegible]—Mr. Ritchie replied: The total quantity of spi[illegible] during the year ended March 31st, 1903, was [illegible] The quantity of home made spirits used for [illegible] period was 3,574,733 proof gallons. I have no means of knowing the quantities used for rectifying and compounding. English spirit is used in the warehouses at Leith but I have no means of knowing the quantities. The materials from which English spirit is usually distilled are malt, unmalted grain, molasses, sugar, glucose, and rice. No doubt beet molasses is used to some extent but I have no means of knowing the quantities.

Mr. T. M. Healy asked the Chancellor of the Exchequer whether any official information had reached him that in preparing whisky for the market frauds were practised in bond by the users of patent still spirit under the supervision of the Government officials; whether he would consider the advisability of bringing the sale of spirituous liquors under [illegible] Sale of Food and Dr[illegible] Acts in the same manner as [illegible] as both these spirits vary considerably in their chemical characteristics only an approximate estimation at best could be made in the case of a blend of which the origin and constituent ingredients were unknown.

Mr. HEALY Has the right hon gentleman seen a statement on the subject in THE LANCET?—Mr RITCHIE : No, I have not

Granard Union Hospital.

Mr. TULLY asked the Chief Secretary to the Lord Lieutenant of Ireland whether the Local Government Board could state the decision arrived at as the result of the sworn inquiry in Granard Union into the action of the medical officer and his management of the union hospital.—Mr. WYNDHAM replied : The decision has not yet been come to. It will be communicated in the ordinary course to the guardians

Nursing Arrangements in Irish Rural Districts

[illegible] at Strokestown was caused by the reports of the Board's medical inspector. The result of the inquiry established the recommendations of the inspector. The inquiry at Boyle is proposed for similar reasons

The Midwives Board.

Sir WALTER FOSTER asked the Secretary to the Board of Education [illegible] board.

Malarial Fever in Uganda.

Mr. HERBERT SAMUEL asked the Under Secretary of State for Foreign Affairs whether he was aware that huts had recently been built at Entebbe for a number of natives belonging to the Uganda Marine and their families in close proximity to the houses of [illegible] spread of [illegible] se huts to [illegible] the situa [illegible] e careful [illegible] fficer who [illegible] ave a free [illegible] received upon the quality of the water have not been unfavourable The local authorities have a free hand within reasonable limits and are alive to the importance of the question

Physical Training in Scotland

[illegible] of the Scottish Education Department and steps are now being taken, along with the Board of Education, to nominate a joint committee for the purpose indicated. It is hoped that the committee will begin work shortly.

[illegible] sentatives of those interested in order to obtain their views as to the recommendation referred to and the means by which it can be carried out. When their lordships are in possession of these views they will consider what, if any, proposals may be submitted to the Treasury as to the financial arrangements

FRIDAY, MAY 8TH.

Vivisection

Sir FREDERICK BANBURY asked the Secretary of State for the Home Department if he would state under what certificate the operation on a brown dog was performed at University College Hospital on Feb. 2nd last, and whether, seeing that a second operation was performed upon this animal before the wounds caused by the first operation had healed, he proposed to take any action in [illegible] replied The operation to which I [illegible] was performed under Certificate C [illegible] was an unhealed wound in the bod[illegible] made very shortly before by another licensee for the purpose of examining the condition of an organ upon which he had previously carried out an operation, from which the animal suffered no ill effects. Previously to the making of the incision the animal was placed under anæsthetics and while still in that condition was brought into the theatre for the purpose of the experiment under Certificate C During the whole of the latter the animal continued under anæsthetics and was eventually taken away and killed before it recovered consciousness In these circumstances there appears [illegible] to take [illegible] for the Home Department if [illegible] olding certificates to practise [illegible] ge, the qualifications of the operators, the nature of the certificates which they respectively held, and the source from which they obtained the dogs on which they experimented —Mr. AKERS DOUGLAS replied The information asked for, with the exception of the last item, is contained in the Annual Return of Experiments on Living Animals, of which the volume for the year 1902 will be issued very shortly. I have no information as to the source from which the animals are obtained.

Glycerinated Calf Lymph

[illegible]

Guards' Hospital, Westminster.

Captain JESSEL asked the Secretary of State for War if he would [illegible] BRODRICK replied The mild varieties only of infectious diseases which do not require notification under the Infectious Diseases Act are treated at Rochester-row Hospital, such as measles and mumps. There is considered to be no danger of infection being spread to the boys of the school mentioned.

MONDAY, MAY 11TH.

Another Lymph Question.

Mr. WEIR asked the President of the Local Government Board if he would state the number of private establishments in Great Britain for the production of a[illegible] unable to state the num[illegible] The hon Member will, [illegible] in an article in THE LANCET of June [illegible]

Mr WEIR also asked the Home Secretary whether his attention had been called to an experiment made on a dog on Feb. 2nd last at the London University College and whether he would take steps to secure that such experiments shall be discontinued or conducted only in the presence of a Home Office inspector and while [illegible] the [illegible] I [illegible]

TUESDAY, MAY 12TH.

Royal Commission on Arsenical Poisoning

Sir CUTHBERT QUILTER asked the President of the Local Government [illegible] in January, 1901, was likely [illegible] rstand that the commission [illegible] s about to prepare its final [illegible] state when it is likely to be issued

WEDNESDAY, MAY 13TH.

Another Vivisection Inquiry.

[illegible] e Secretary whether the dog [illegible] ty College on Feb 2nd was [illegible] the theatre —Mr. AKERS-[illegible]

Appointments.

Succ[illegible] Public Institutions, [illegible] this column, are [illegible] ected to the Sub- [illegible] morning of each [illegible]

CASE, HENRY, L R C P, L R C S Edin., has been appointed Medical Officer and Public Vaccinator to the Withnell district of the Chorley Union

N.B —A fee of 5s. is charged for the insertion of Notices of Births Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A LADY'S VIEWS.

OUR attention has been called to an article published in the *Star* of Wednesday, April 22nd, entitled "The Medical Trade Union," and written by a Dr. Helen Bourchier. The article is the usual rubbish to be found in many lay papers when they begin to discuss the medical profession at large, as is sufficiently indicated when we say that the "Medical Trade Union" appears to be one of the lady's terms for the General Medical Council. The only point of the whole article that is worth attention is the fact that it should have appeared in a well edited evening journal with a deeper sense of the responsibility which it owes to the public than many of our popular newspapers. The articles in the *Star* on literature and art are sound honest journalism With regard to matters medical the paper is frankly antagonistic to our profession, probably from a desire to show that it speaks for the public and not for a section. We do not suppose, however, that it desires to give currency to complete misstatements. We should like to know how such rubbish as this found its way into the columns of a responsible paper. "A doctor must belong to the General Medical Council, or by Act of Parliament he is forbidden to sue for his fees in a Court of Law," &c. Thus Dr. Helen Bourchier, who seems to think that all the 37,000 registered practitioners are members of the General Medical Council, a body which she has mixed up with the British Medical Association or with the official roll of the profession. The gist of her article is to strike a note of warning against the Medical Act Amendment Bill because "it proposes to give greater powers to the already too powerful General Medical Council." "First," she says, "the Council is to have power to suspend a registered practitioner for any length of time it sees fit." She is of course utterly unaware that the reform is being taken in the direct interests of men whom she is trying to regard as victims—viz., those who fall under the unfavourable notice of the Council. At the present moment the General Medical Council can inflict but one form of punishment All "*infamous conduct in a professional respect*," whether it be the procuring of criminal abortion or the unfortunate wording of an advertisement, the traffic in secret cures or the improper use of an assistant, is punished in the same way—the offender is struck off the roll of the medical profession. The desire of the Council is to have some scale of penalties so that this tremendous punishment may not be meted out equally for the serious offence and the venial lapse. The power that the Bill would give the Council is the power of mercy—a discretion enabling it to make the punishment fit the crime, whereas now it is compelled to punish great and small offenders alike. The body that is trying to effect this reasonable change is stigmatised by this lady as "the modern Star-Chamber commonly called the General Medical Council." With regard to the writer of the article in the *Star*, we have a shrewd idea that nothing that we could ever say would lead her to alter her views. Not being herself on the Medical Register and having no official status entitling her to practise medicine in this country she girds at the General Medical Council perhaps to show that it is not her want of registrable qualifications but the narrow organisation of the Council that prevents her from practising medicine. We know this view · it is the line taken up by every advertising quack in the country. The General Medical Council is not above criticism, for the Acts of Parliament by which it was created and under which it has been amended are imperfect. But the General Medical Council exists for the protection of the public and not of the medical profession, as everyone knows. By keeping an official roll it makes the action of the public in consulting quacks a wilful act, and by purging that roll of wrongdoers it safeguards the public's interest

ERYTHROXYLUM COCA.

ACCORDING to the British Pharmacopœia the dried leaves of *Erythroxylum coca*, from which cocaine is extracted, are imported from Bolivia and Peru The May number of the *Illustrated Scientific News* states that this plant, among others of medicinal value, is now being cultivated experimentally in the Victoria Botanical Garden of the Cameroons, German West Africa, but a firm of alkaloid makers in Germany, to whom some of the leaves were sent, found them to contain only 0 28 per cent. of total alkaloid.

SOLICITORS, THEIR CLIENTS, AND THE MEDICAL ATTENDANT.

To the Editors of THE LANCET.

SIRS,—I should be glad of your opinion on the following case. I was called in by a Miss C to attend her I was informed by my patient that her account would be paid by her solicitors and I sent it to them, my patient writing to them at the same time requesting payment. The solicitors objected to the amount of the fees, although they acknowledged that they were the usual ones and that they had instructions from my patient to pay the account as it stood. In spite of this I was compelled to reduce my charges to the extent of £3 in order to get it settled. My patient told me on subsequent visits that pressure was being brought on her to change her medical attendant but that she had no wish to do so. However, that this pressure was successful is proved by the fact that three days after my visit to my patient, and when she had assured me of her confidence in my care and attention to her, I received a curt letter from the solicitors informing me that they had written instructions from Miss C to dismiss me from the case and call in another medical man. No explanation was given me of this extraordinary conduct of a firm of solicitors to their client's medical attendant and it appears to me that if the medical man in attendance in a case is to be in the power of a solicitor in this way his position will be unendurable, but I hope it to be a unique example of a solicitor exceeding his duty and unduly using his position to have a medical man dismissed from his patient. I am, Sirs, yours faithfully,

May 12th, 1903 M.R C S. Eng.

*** It is to be regretted that our correspondent made any reduction in the usual fees at the instance of the solicitors, unless he knew that his patient was in pecuniary difficulties. We cannot express any opinion upon the attitude taken up by the solicitors generally, as we know nothing of their client or the circumstances in which they are acting for her.—ED. L.

NO MORE DEATH.

THE following extraordinary card has been brought to our attention by readers living in one of the southern suburbs. It is circulated publicly and is presumably a counterblast upon the part of the Christian Scientists to the just ridicule of their absurdities which recently emanated from the pulpit at Plaistow, Kent (*vide* THE LANCET, March 21st, p. 823).

GLORIOUS NEWS!!

CHRISTIAN SCIENCE FOR ALL!!

No more Aches and Pains! No more Sighs, Sorrows and Suffering!
No more Medicines, Crutches and Splints! No more Operations!
No more Church Services and Sacraments!
No more Easter Offerings! No more Doctors' Bills!
NO MORE DEATH!
Only have Faith. Faith and Illness cannot coexist.
Waste no more money on Churches and Hospitals; Burn them or lock them up.

DOWN WITH PARSONS AND DOCTORS AND LIVE FOR EVER!!

If this silly sect outlives the attacks of Mark Twain it evidently contains within itself the elements of its death No creed, the followers of which could produce such desperate rubbish, can hope for support from thinking people, and some of the persons who at present contribute to the maintenance of Mrs Eddy as a divine person will soon cease from bolstering up a faith that is born of hysteria and nurtured on lies What does "No More Death" mean in this circular? Does any Christian Scientist want to wager that Mrs. Eddy will live till, say, she is 100? It has been suggested that the card has been manufactured with the intent to bring *Christian Science* into ridicule Perhaps, but we think that the composition looks genuine

WANTED—A HOME

To the Editors of THE LANCET.

SIRS,—I wish to hear of an institution where a female patient could be given rest and massage treatment at moderate expense and shall be greatly obliged to any correspondent who may be able to inform me of such. I am, Sirs, yours faithfully,

S. KELLETT SMITH, F.R.C S. Eng.

23, Russell street, Liverpool, May 11th, 1903.

A WARNING.

To the Editors of THE LANCET.

SIRS,—May I through the medium of your columns warn intending applicants for the post of "doctor" to the St. Luke's Hospital, Chemulpo, Korea, to make a searching inquiry into the nature of this [illegible]

I am, Sirs, yours faithfully,

W. A. ANDERSON, M B. Edin.

Denbigh road, Bow. E. May 9th, 1903.

THE PROSTITUTION OF THE POST OFFICE

THE Post Office having confessed its inability, or its unwillingness, to do anything to stop the flood of betting circulars, lottery advertisements, and notices of quack medicines which daily and hourly infest the letter-boxes of His Majesty's lieges we are going to refer to the matter again. Various correspondents have forwarded to us certain slips of blotting paper which they have received from America in open envelopes The blotting paper, against which as blotting paper we have nothing to say, is printed over with testimonials to the virtues of a certain drug and, moreover, emblazoned in large letters [illegible] evidently intended to be laid on a writing table [illegible] sufferings of women? Thus, for example: "Mrs. E. B., aged 29, married four years, no children, had suffered every month with dysmenorrhœa and a somewhat fœtid discharge." We are sorry to see, too, that the slips of blotting paper in question tell readers that the drug can be obtained through an English agent. The drug in question may be a good one for all we know but it is not fitting that any respectable firm should advertise its wares in this manner and it is still less fitting that His Majesty's Postmaster-General should make himself the agent for the transmission of such nastiness.

POINTS IN ETIQUETTE.

To the Editors of THE LANCET.

SIRS,—Permit me to "propound a case for your arbitrament." L.R.C.P. is a general practitioner in attendance upon a patient, Mrs. B. Dr. C is a consultant, a Fellow of L.R.C.P.'s college and a former lecturer in the school where he was educated. Mrs. B, desiring a second opinion, writes (irregularly, of course) to Dr. C, requesting his advice. Dr. C, on learning that L.R.C.P. is in attendance, declines to see her except in consultation and advises her to communicate with L.R.C.P. and to ask him to make the necessary arrangements. Mrs. B thereupon requests L.R.C.P. to arrange a consultation with Dr. C. L.R.C.P. declines to do so, but writes to Dr. C, saying that a consultation is unnecessary, but that, since he (L.R.C.P.) understands that Dr. C wishes to see the patient, he may do so if he likes. Dr. C informs L.R.C.P. that it is not he who wishes to see the patient, but the patient who wishes to see him, and declines to have anything to do with the case except in consultation. L.R.C.P. replies, inclosing his communication in an envelope addressed to "Mr. C." He again declines the consultation on the ground that Mrs. B is quite satisfied with the treatment she is receiving and accuses Dr. C of interfering with his patient. To this Dr. C replies, regretting the tone of L.R.C.P.'s communication, again repudiating the charge of interference, and stating that the rules of the profession require a consultation. Has L.R.C.P. any grievance against Dr. C? Is he justified in accusing him of interference? Is L.R.C.P. within his right in declining the consultation? I am, Sirs, yours faithfully,

May 7th, 1903. IATROS.

*** The right to demand a consultation rests with the patient quite as much as with the general practitioner. Therefore if Mrs. B wishes for a consultation L.R.C.P. must agree to her wishes or withdraw from the case. From the account before us Dr. C. has acted perfectly properly and L.R.C.P. has not.—ED. L.

PRIZE FOR A DUST-ARRESTING RESPIRATOR.

UNDER the terms of the Benjamin Shaw trust the council of the Society of Arts is offering a prize of a gold medal, or £20, for the best dust-arresting respirator for use in dusty processes of manufacture and in dangerous trades. Full particulars of the conditions which the apparatus will be required to fulfil can be obtained from the secretary of the Society of Arts, John-street, Adelphi, London, W.C. The competition is not limited to British subjects and is open until the end of the present year.

A CURIOUS ADVERTISEMENT.

THE following curious advertisement appeared in the *Shields Daily Gazette and Shipping Telegraph* of March 17th last. This paper, by the way, claims to be the oldest daily newspaper in the provinces, having been established as an evening daily in 1855, although originally established in 1849 as a weekly newspaper:—

PUBLIC NOTICES.

A DEBT OF HONOUR due to Dr. Bains for the most prompt and careful attention paid to my beloved wife during her severe illness, trusting that the people in the Borough of South Shields will patronise his profession; we are also very greatly indebted to all our friends for the sympathetic kindness and attention given to my wife during her trouble; also the kindness and respect shown to her by our friends from Tynemouth Castle and in the vicinity of Tynemouth on the 15th inst., when on that date she was interred at Harton Cemetery. I also wish to bring to notice the manner in which my most esteemed friend, J. Milnes, catered for the same, and sincerely trust that our friends in South Shields will appreciate and patronise 84 New Market Dining Rooms.—Signed, JABEZ HAWKINS SHEPPARD
and A. H. EWART,
181 Victoria Road. her most bereaved husband and father.

We do not see the name "Bains" in the Medical Register or the Medical Directory, but we trust that if the gentleman referred to is a qualified medical man he received not only the "Honour" but something more substantial.

POST-MORTEM POLITENESS.

A CORRESPONDENT of the *Law Times* sent to that journal a letter in the course of which he said: "Some time since we gave notice to the Land Registry of the deposit of a land certificate which had been made by way of creating an equitable charge. Then the equitable mortgagee for whom we gave the notice died and probate was registered at the registry. Shortly afterwards the equitable charge was paid off and all the executors signed and sent to the registrar a withdrawal of the notice of deposit. Thereupon the registry thoughtfully posted a notice addressed to the deceased at his earthly place of business which runs as follows: 'To A.B.—An application, dated the 25th March, 1903, signed by your executors and purporting to be a withdrawal of notice of deposit of land certificate affecting the title above referred to, has been left in this office for registration. If you have any objection it should be stated in writing.'" One of the executors thereupon wrote to the deceased's solicitors saying that as he was not in communication with the other world he could not say whether the deceased had any objection or no. As we believe that an executor has no *locus standi* until the party for whom he is executor is dead we should very much like to know why the registry wrote to a dead man and in what manner they expected him to reply. But the delicate feeling of the registry is beyond all praise and the only parallel of which we can think is the case of a poor woman whose two children had been invited to a Christmas-tree at a hospital. On the appointed day only one child, a girl, arrived and on the house physician asking where her brother was she said, "Please, doctor, mother said I was to say she was very sorry she couldn't let Tommy come." Whereupon the house physician expressed a hope that Tommy's absence was not on account of illness and received the startling answer, "Please, doctor, 'e's dead."

A CORRESPONDENT asks us in connexion with an analytical report which appeared in our columns upon a natural mineral water (Hunyadi János), What exactly is the meaning of "constant composition?" Does the expression "a composition that is constant" convey a clearer idea to our correspondent? If not, and if it be possible to make what is already plain English plainer, we may add that the expression means that the proportion of dissolved salts in the water is always the same, that the ratio of salts to each other does not vary, and that therefore the therapeutic effect may be expected to be the same with the same doses.

◆

P. Q.—1. A stamp must be affixed by anyone desiring to give a legal receipt for a sum of money of £2 or over. We cannot enter into the question of the exceptions to this general rule. The person who has paid the money can insist upon the receipt being given to him in legal form, but as a matter of practice no such demand is made in very many instances, while some firms supply their employés with receipt forms already stamped. 2. As a rule the person who buys a practice protects its sale value, in case he should desire to sell it again, by preventing the occurrence described by our correspondent. The wording of the agreement will settle the question.

Agricola.—The method of payment is as novel to us as it is to our correspondent. We are hardly prepared to express any opinion upon its possible working, but we think that perhaps 250 monthly tickets would be about represented by the suggested sum. The arrangement must be tried before any definite verdict can be passed on it.

Vendor.—We do not think that there is any established custom, although it seems to us a fair thing to ask three years' gross receipts. The circumstances are such that it would be well to employ an agent, giving him some discretion as to terms but fixing, of course, the minimum.

Locum will find in various issues of THE LANCET all the information he requires. Different States of the United States have different regulations with regard to medical practice. *Vide* THE LANCET, vol. ii., 1896, pp. 7[illegible]3 and 969.

Justitia.—We quite agree with our correspondent that the matter hardly needs comment. That being his opinion we wonder why he sent us the particulars.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C, are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

An Address

ENTITLED

SOME REFLECTIONS, MAINLY ETHICAL, ON THE PRESENT POSITION OF OPERATIONS IN THE PRACTICE OF SURGERY.

Being the Annual Oration of the Medical Society of London, delivered on May 18th, 1903,

BY SIR WILLIAM H. BENNETT, K.C.V.O., F.R.C.S. ENG.,

SENIOR SURGEON, ST. GEORGE'S HOSPITAL, ETC.

MR. PRESIDENT AND GENTLEMEN,—My first duty is to tender to you, Sir, and to the council of the society my thanks for the compliment which it has been thought right to pay me in the invitation to deliver your annual oration. I must at once confess that I have only been induced to place myself in a position which is so much beyond my province by the feeling that it would be ungracious to decline an invitation which conveys so much.

I am sure that I am right in saying that only those whose experience extends backwards beyond the time when the great work of Lister was made known and its influence upon the work of surgeons generally became manifest, can in any degree truly realise the enormous changes—I might almost say miraculous changes—which followed in the practice of surgery. I am therefore thankful that my medical education commenced before the Listerian era, which, after all, is not so many years ago—a time when septic diseases, like erysipelas, cellulitis, osteomyelitis, and kindred conditions, were common consequences of operations and formed a large proportion of hospital work—a time when the salvation of the patient and the reputation of the surgeon not infrequently depended upon the appearance of the pus which was called laudable—a time at which the author of one of the most successful text-books of the day took the opportunity of congratulating his readers that the science of surgery had advanced so far that but little further progress could be looked for, and when one of the foremost surgeons in London chose as the subject of his presidential address at the Clinical Society, "Pyæmia in Private Practice," and gave many illustrative cases. The practice of surgery in times like those, when the main object was the avoidance of operations because the results were so often disastrous and when an uncomplicated progress after operation was the exception, necessitated an amount of consideration in deciding upon the radical treatment of a case and an alertness in watching and dealing with the subsequent complications which cannot be appreciated by those whose experience has commenced in later times. The complete realisation of the fact [illegible], thanks to Lister's labours, operations could [illegible]rmed with comparative safety, naturally not onl[illegible]he radical treatment of many conditions [illegible] had been allowed to end fatally without any [illegible]pt to obviate such a result, but ushered in [illegible] operation of innumerable conditions which, [illegible]dangering life, were the cause of so much [illegible] many individuals as materially to diminish the [illegible]sefulness of the general community. And as the con[illegible]e in the safety of operative methods grew with surgeons generally, the treatment of certain conditions, in themselves harmless at first but possessing potentialities for evil later, became common, and so arose the class of operation which may be called preventive. Finally, there came the utilisation of operations for diagnostic purposes—for example, the opening up and inspection of the abdominal, thoracic, and cranial cavities, leading ultimately to the

APOTHEOSIS OF THE EXPLORATORY OPERATION.

The promise of such enormous benefits from operative treatment which could be used with comparatively small risk was followed by an amount of energy and enthusiasm in the direction of this radical form of treatment and in the invention of operations which came at one time perilously near to the limits of reason and there seemed a danger that the operation influence would reach to the dignity of an obsession—a condition of things which hardly tended to the best interests of surgery. The pendulum has in due course commenced its backward swing and a position has now been reached from which the rational bearings of surgical operations generally may be considered in relation to the risks which they entail, the benefits which are derivable from them, and the limits which legitimately control their application.

In what follows it must be understood that I have little desire to influence and still less to teach; that I am merely giving views and describing impressions which are those of one who during an experience which extends from the time just anterior to the commencement of the period of surgical cleanliness has been carefully watching the progress and general trend of surgical affairs and who, I have reason to believe, enjoys a fair share of operative work in London at the present time and so may be allowed to have some knowledge of the failures as well as of the successes which are necessarily associated with a rather large experience. Speaking generally, I am compelled to say that it seems to me that the tendency towards operative measures, although less than it was a few years since, is still, on the whole, too strong, and that operations are yet approached in too light a spirit, not for the reasons to which I have already referred, but because a prolonged familiarity with them has led to an under-estimation of the risks which they entail and to a forgetfulness of the defective results which, more often than is commonly thought, follow upon them. I am further bound to feel that the present position of things tends far too much to the reduction of the surgeon to the position of the mere mechanic. Indeed, it is not long ago that a surgeon is reported to have said that he considered himself nothing much better than a good carpenter—a statement which was, if I may be respectfully allowed to say so, a greater tribute to his modesty than to his sense of appreciation of the realities of his profession.

THE FOUR STAGES OF SURGICAL LIFE.

The working life of every surgeon may, I venture to think, be divided into three principal stages. In the first, or [illegible] are apt to obscure wider and often more important issues in the way that a penny piece, if placed sufficiently near the eye, will obscure the sun. Towards the end of this stage those whose sense of infallibility is not too strong begin, I fancy, to realise the truth of what may be expressed by an ancient classical adage, slightly modified: *Nemo repente fit chirurgus.* At about this time in the evolution of the surgeon the tendency shown rather later to operate less freely and apparently with less energy sometimes leads to the conclusion by those who are yet in the early stage of their development that this is due either to indifference or to an inability to keep abreast of the times, the real factor in the matter, which is the dictate of increasing experience, being overlooked.

In the second stage the gathering of experience and the lessons of some failures and disappointments lead in the majority of men to maturer judgment and a better understanding of the proper relation of things. It is towards the end of this period that the greater number of surgeons begin to be rather less aggressive in the direction of the purely operative treatment and show indications of approaching it with more consideration than hitherto, an attitude which is the result, as I have already said, of increased experience and a more accurate knowledge of the real value of operations as such. It is at this time that a sober retrospect on the part of those whose sense of proportion is sound will, I am confident, recall to mind more instances than one in which an operation performed in all good faith had better, for the good of the patient and perhaps for the reputation of the operator, have been left alone.

With the third stage comes the inclination for the surgeon to confine himself to certain operations with which he feels himself most at home and thus to some extent his practice becomes eclectic. The increase of experience and a maturer judgment at the same time becoming more prominent characteristics he is enabled to exert a far-reaching influence of the greatest value.

There is a fourth stage, of course, in the surgeon's life when, happy in the contemplation of an honourable career well spent, it is to be hoped that he has much money at the bank—a time when, although operations [illegible] things of the past, there remains that never-failing judgment, the outcome of a vast experience the importance of which it is impossible to over-estimate, although I fear at times it is not altogether appreciated at its full worth by some of us.

Operation Risks in Mortal Cases.

I presume that it cannot seriously be contended that any operation can be made absolutely safe, even if it be assumed that the operator is as perfect as an operator can be, for apart from merely accidental risks some account must be taken of the effects of the anæsthetic, the constitutional peculiarities of the patient, the circumstances in which the operation is performed, and the qualities of those who assist in its completion. The risk incurred may be an immediate danger to life, it may be a possibility of leaving a worse condition than existed before the operation, or it may be merely the chance of defective results.

With regard to the danger to life, apart from certain accidental risks which must be connected with all operations, it is clear that in any mortal condition which seems susceptible to relief by operation no risk is too great to run provided that there is a real chance of success, but I do not think that the mere fact that a patient is apparently bound to die unless operated upon is in itself a justification for operation; and operations upon moribund and on semi-pulseless people, save in very exceptional circumstances, seem to me to be mischievous and unscientific, since they cannot, from the nature of things, benefit the patient and they reflect but poorly upon the practice of surgery. The amount of risk which can be justifiably run in these mortal cases depends greatly upon the question as to whether the lesion is due to curable—that is, probably non-malignant—conditions or whether it is caused by malignant disease or by some other incurable state. It is obvious, I suppose, that there is practically no limit, as I have already said, to the risk which may be run in dealing with a curable condition, whilst in a case of malignant disease, for example, in which the operation as a rule may be regarded as palliative, grave consideration should be given to the question of risk before embarking upon a treatment which at the best can probably only lengthen life for a period and may shorten it materially without affording much prospect or possibility of cure. On the other hand, the chance of shortening life by a little time may be legitimately taken when a cure is practically sure if the case turns out to be successful from an operative point of view. In all cases of this type the point of paramount importance is the realisation that the primary object is to save life and not necessarily to perform an ideal operation. I make no doubt that more than one life has been sacrificed by proceeding to the completion of an academic operation which might have been saved by the performance of a less serious proceeding in the first instance. This observation, although it applies generally to a number of cases, such, for example, as extensive disease about the neck and throat, the rectum, and other parts, seems to me to possess especial force in connexion with many of the large growths revealed by abdominal exploration, the risk of removal of which is generally altogether out of proportion to the benefit likely to be derived from the treatment, the mortality in such cases being high, whilst not a few really show no lethal tendency if the disease is left *in situ* after free exposure, and in some the disease finally disappears. Having regard to all the circumstances in cases of this type it appears to me that in the vast majority the proceeding to the extirpation of masses of disease which entails, for example, the taking away of large portions of the great blood vessels or other vital parts is rather an academical demonstration of the possibility of removing a growth than a treatment for the benefit of the patient, especially when it is remembered that, even with our present knowledge, it is practically impossible to say whether a growth is malignant or whether it is not by any other test than its clinical behaviour. The three following cases which have occurred in my practice within the past two years are sufficient to emphasise this fact.

Case 1.—A boy, 14 years of age, was found to have an apparently malignant growth of the right kidney and surrounding tissues. The vena cava was involved in the disease; many outlying nodules distinct from the main mass existed. One of these was removed and proved after examination to present microscopically all the characters of typical sarcoma No attempt at removal was made. The whole disease disappeared and the boy is now in the navy.

Case 2.—A young woman, aged 28 years, had abdominal section performed with the view to the removal of a mass on the left side of the abdomen below the umbilicus which seemed to be connected with the uterus. Upon exposure a large, and so far as could be judged a typical, mass of malignant growth was seen involving the omentum and the uterus, lapping around the left iliac vein and artery, with which it seemed to be inseparably connected. Secondary nodules in large numbers were scattered in the omentum in the immediate neighbourhood. No attempt at removal was made. The whole disease has apparently disappeared and the patient is in good health.

Case 3.—An abdominal section was made with a view to the removal of a tumour apparently involving the cæcum in a man, aged 48 years. The mass, which involved the cæcum as was expected, had the appearance of malignant disease; it was fixed and extended inwards by a flattened process to the middle line. In this the vena cava was imbedded. No evidence of obstruction had occurred and as the active growth appeared to be in a direction away from the bowel nothing further was done. It is now three months since the operation; the mass is smaller and is steadily decreasing, while the general health of the patient is continuously improving.

I have no doubt that in each of these cases the removal of the disease was mechanically possible, but it is hardly likely that all the patients would be alive now if the completion of ideal operations had been effected.

I mention these cases not because they indicate that completion of ideal operations should not under proper conditions be effected, but because they show clearly enough that even when operation is in progress the result of a case may depend upon much more than the dictates of mere craftsmanship. A more striking instance, perhaps, than any one of these was the case of a nurse who became a patient in St. George's Hospital on account of hæmatemesis in whose abdomen a large mass could be felt which proved, as was believed before laparotomy, to be connected with the stomach. It had upon exposure all the appearances of a large carcinomatous plate involving two-thirds of the anterior and under surface of the organ towards the pyloric end which was involved in the disease and was also adherent to a mass of glands which lay beneath it. The case occurred at about the time when the complete removal of the stomach was under discussion and I should, if the patient's condition had offered any hope of real success, have removed the greater part of the organ. As it was nothing was done; the mass disappeared and the patient resumed her work. I mention this case as it provides an excuse for referring to a remarkable difference existing in the experience of surgeons in malignant, or what seems to be malignant, disease of the pylorus and the parts continuous with it. It happens that my experience of the surgery of the stomach is large, but in all my dealings I have only met with three cases in which I have thought pylorectomy worth performing. The other cases have either been too advanced to justify the treatment or of too doubtful a nature to lead me to think it proper. All these doubtful cases have been treated by gastro-enterostomy, with uniformly good results. In a very striking case, in which several of those present were convinced of the malignancy of the disease and upon which I operated by gastro-enterostomy in 1887, the first case of the kind at St. George's Hospital, the man is alive now and following the occupation of a waiter. Seeing the large number of pylorectomies published by other surgeons in different parts of England it is clear that either my practice differs altogether from theirs or that the cases which come in their sphere of action are of a different kind from those with which I meet. However this may be, I am content with the result of my own experience which emphasises the truth of a dictum for which I have a profound respect and which could be illustrated by endless cases—namely, that when an equally good result is obtainable by two operations, one being distinctly less dangerous than the other, the best practice is to choose the milder method, although for the moment it may appear less brilliant in itself and perhaps less obvious in its immediate result.

Some Effects of Familiarity with Operations upon Their Use.

The effects of familiarity with operations in leading to their adoption in a manner which one cannot help feeling is not always quite discriminating are best seen in connexion with the operative treatment of certain conditions which are dealt with radically, either from the point of view of pure expediency or for preventive purposes—conditions, in fact, in which operation cannot be regarded as actually necessary and in which the proper application of the treatment must therefore depend entirely upon the judgment and experience of the surgeon concerned, the justification for an operation being principally its safety and a certainty, or at all events the strongest possible probability, of the desired result being assured In many of such cases it cannot, I think, be denied that the operative treatment has with some of us degenerated—I use the word advisedly —into a mere question of routine And it may be said without reservation that if a treatment becomes a routine method the danger of suppression of individual judgment in connexion with it becomes a reality For the better understanding of this contention, although many other illustrations could be offered, it is convenient to consider only two conditions which must be more than familiar to all of us—that is to say, disease of the appendix and varix. The removal of the appendix after the occurrence, or recurrence of certain symptoms may, I presume, without exaggeration be described as a routine practice now with many surgeons At the same time, it cannot be contended that the removal of the appendix is always called for or that it invariably relieves the symptoms for which the operation has been performed For the proper application of a treatment which may itself cause death (fatal results do sometimes follow the operation of removal of the appendix even in the quiescent stage), may not relieve the symptoms for which it has been carried out, and is sometimes followed by grave complications such as for example, extensive thrombosis, must clearly demand an amount of judgment in its application which is altogether incompatible with mere routine Further, in relation to this matter generally, it seems to me that the habit of frequently operating in any given condition tends automatically to an inclination to over estimate its gravity It is, for example, by no means certain that the lethal tendency of recurrent appendicitis is as great as we have come to suppose Many people live the ordinary span of life without operation who have been the subjects of frequently recurring attacks of appendicitis—a statement which receives considerable interest from the fact that it would be easy to indicate a number of persons in the medical profession who, whilst they are the subjects of recurrent appendicitis, show no great anxiety for operation

I have said that the removal of the appendix does not always immediately do away with the symptoms for which the operation had been performed The defective result in these cases depends, it seems, upon the serious implication of the cæcum itself in the disease. It is not so uncommon as is generally supposed for recurrent attacks of symptoms indistinguishable from those which occurred before the removal of the appendix to follow after the operation, either immediately or after an interval, in cases in which the original attacks have followed upon malaria dysentery, or typhoid fever, the explanation probably being that in such cases the disease is liable to be cæcal in its origin There have come under my notice cases in which the appendix has been removed for the ordinary symptoms of appendicitis so called, in which attacks indistinguishable from what is commonly called appendicitis followed after the operation It is true that after repeated subsequent attacks the symptoms gradually wore themselves out, but so they might have done in the absence of operation altogether During the late South African war I had a considerable experience of operations in cases of appendicitis in men invalided on that account and of these three cases in which symptoms arose after dysentery and malaria showed no immediate improvement at all after the operation In each of these cases the cæcum was at the time of operation seen to be the main seat of disease, the appendix in each, although it could hardly be called normal, was so slightly involved that no stretch of imagination could have saddled it with the cause of the symptoms and my impression is that in the light of subsequent events these cases would have been as well without operation as with it It would therefore seem that it might be worth the expenditure of some pains and some time in endeavouring to arrive at a diagnosis without operation between cases in which the cæcum is the original seat of disease and those in which the appendix is primarily at fault, an observation having a practical bearing to which I shall refer for another purpose a little later

Illustrations of a less debateable kind of the point I have just now in view may be afforded by cases which in themselves have no lethal tendency at all, such, for example, as uncomplicated varix of the lower limbs, which provides a large number of operations at the present time I know of few conditions which require the exercise of more judgment in arriving at a proper decision as to the desirability of operation than these cases of varix do The number in which operation is really beneficial is very small in comparison with the number of cases met with, moreover, the size of the veins bears no relation to the necessity for operation, inasmuch as in many of the cases in which the veins are largest operation is altogether unnecessary, and indeed often unjustifiable, mere abnormality having to be distinguished from disease Setting aside, therefore, such patients as come up for treatment to satisfy the requirements of the public services, the cases of this class in which operation is really indicated are few, save those in which objective trouble, such as pain or rapid increase in size, is present

Now, the operation for varix in subjects between the ages of 18 and 45 years may in sound subjects be regarded to be as safe as any operation can be and need not therefore in itself be regarded seriously—a fact which, I cannot help feeling, leads to the performance of operations in a certain number of cases of this kind which would not be so treated if the risk of the proceeding were sufficient to lead to a careful consideration of the bearings of the matter That this is so I am compelled to conclude by the fact that cases come under observation in which operations upon varix of the lower limbs have been carried out for the relief of symptoms undoubtedly due to flat foot which were subsequently relieved by the ordinary treatment for that affection And cases from time to time come under notice in which pains resulting from nervous disease have been apparently assumed to be due to extensive varix, which has consequently been operated upon with a view to the radical cure—an error of judgment which might have been avoided if the patellar reflex had been tested Had the treatment here been of a more dangerous kind I have no doubt that a sufficiently thorough examination would have been made to prevent the performance of operations which were more than unnecessary It would, if time allowed, be easy to give further illustrations of this kind

THE SAFETY OF OPERATIONS IN RELATION TO THEIR PERFORMANCE IN CERTAIN CASES

Going a point further I think it clear that the mere safety of an operation tends to obscure the fact that its results may not be invariably advantageous to the patient, a view which could be supported by fertile examples which would show, in cases in which the condition before operation had given rise to no trouble and in which, in fact, the radical treatment had been carried out for purely expedient or preventive purposes, that the consequences following are sometimes regrettable The percentage of cases in which unsatisfactory results follow is, of course impossible to ascertain, but the fact that such results do ensue is clear, because I see in the course of my experience—which I suppose cannot be very different from that of other people—cases in which operations performed by various surgeons are followed by such results Taking varix again, for example, cases occur in which thrombosis, permanent cold extremity, chronic œdema, and acute neuralgia follow operation in people who previously had suffered no inconvenience at all As a good example of this sort the last case of the kind which has come under my notice is worthy of mention The patient was a young girl of a highly sensitive temperament who, being distressed about some slight varix in both lower limbs, contrived to have operative treatment upon the veins, which had previously given no trouble at all, carried out Thrombosis in both limbs followed the operations and now, months after the treatment she is only just able to resume her ordinary vocation and it remains to be seen whether further trouble will arise It would, I presume, be foolish to contend that the operation would have been performed if it had been thought that any risk to life attached to its performance An interesting point arises here in connexion with the difficulty which presents itself to an operator in determining sometimes whether an operation is finally successful or not, because it is quite certain that a large percentage of those patients whose operations prove in the end unsatisfactory do not return for advice to the surgeon who originally operated, and I have reason to know that instances happen in which the original operator has considered, and sometimes, indeed, in good faith has recorded, a case as successful which has been under the care of another surgeon subsequently either for further operation or in consequence of unfavourable results following upon the original treatment. It is only a short time since that I heard, quite by chance, that a patient upon whom I had operated, as I thought successfully, had been treated subsequently by another surgeon for the same condition, presumably because my operation had failed to effect the object desired. And I have lately seen a patient who has already been operated upon for the same lesion by two surgeons, each of whom is, I believe, under the belief that the operation performed by him has been successful. Indeed, in this respect there is little doubt that many of us live in something like a fool's paradise, a fact which, in the study of statistics, is not to be regarded altogether with complaisance. It is, at all events, quite certain that the true value of a treatment cannot be estimated upon records of successful cases and it is a welcome and healthy sign when a distinguished surgeon, as happened a short time since, thinks it right to publish a series of unsuccessful results following upon operations of which he has had a large experience. In connexion with this question it is, I suppose, superfluous to insist that a successful operation should be held to mean one which achieves the end for which it is performed, whether that be the saving of life, the relief of pain, or any other object. The description of successful operations followed by the death of the patient has been fully satirised by Dickens and others before him and the matter would not be worth mentioning here were it not that apparently serious mention is sometimes made of cases in which successful operations have been performed without the saving of life or attaining some other end which was the real object of their performance. The use of the term "successful" in connexion with operations in such circumstances seems to me to be a juggling with words which is not quite consistent with the traditions of our profession, and that it should be so used is, I think, further evidence of the way in which the overwhelming importance now attached to operations themselves tends to obscure the more vital points at issue and sometimes, it must be admitted, goes dangerously near to leaving in the background the great truth that in all matters of this kind the interests of the patient and not the mere attaining of a mechanical achievement should be the surgeon's first concern.

The Exploratory Operation.

The results of the free employment of the exploratory operation have, on the whole, been greatly to the advantage of the patient and of the surgeon alike, but, as is the case with many other things, an exploratory operation is not always perfect in its results and, moreover, it cannot be regarded as altogether free from risk. It is sometimes said when discussing the propriety of making an exploratory operation that at all events no harm can come of it if no particular advantage is gained. But is this always the case? I find that within a comparatively short time I have been brought in contact with no less than 16 cases in which persistent troubles—arising, it has been said, after abdominal exploration—have been complained of. 10 of these came under observation on account of troubles connected apparently with the operation. In the others the fact of an exploration having been performed was only discovered accidentally in the course of conversation or in the course of examinations made in connexion with matters apparently unassociated with it. In five of these cases large ventral herniæ existed; in three cases persistent pain of an acute kind had followed about the region of the wound; in two there were sinuses; four patients had never been the same since the operation; one had continual incontinence of urine; and one had an ankylosed hip which was stated to have followed upon fever which came on after the operation. Fatal cases are also not unheard of. I have already said in another connexion that results like these in no respect negative the propriety of the exploratory operation as such, but only show that it cannot be regarded always as a trivial proceeding and that it should therefore be undertaken only when it is really necessary and not merely as a routine proceeding. Although the instances of defective results which I have mentioned are confined to the abdomen it would be easy to afford other examples, notably in the case of the knee In one respect, at all events, it is certain that the very free use of the exploratory operation does not make for the good of surgery. It cannot, I think, be denied that, speaking generally, the estimation in which the art of clinical diagnosis—by which I mean bedside diagnosis as distinguished from that of the operating theatre and the clinical laboratory—is held has declined since the free use of the exploratory operation. This must be patent to any acute observer of surgical affairs generally and it must be especially clear to those who are concerned in examining candidates for the various degrees and diplomas, as they have exceptional facilities for judging of the trend of clinical teaching in the various medical schools. In former times, in consequence of the risk generally involved in any but the simplest of operations, and sometimes even in them, it was essential to strain every faculty of observation to endeavour to arrive at a diagnosis before resorting to operation. Now, on the contrary, when the exploratory operation, which can, as a rule, be carried out with comparative safety, is an immediate means of clearing up a difficult diagnosis there is a disinclination to spend a great amount of time in arriving at a conclusion independently of operation which it is thought may be much more easily attained by exploration. In some respects, apart from any question of risk to life or other consequences, this condition of things is not advantageous, and especially is this the case from the educational point of view, for although, as I have said, the exploratory operation may often be a proper resource in the hands of those sufficiently experienced to appreciate its limitations, to the inexperienced and to the ordinary student its too common use is distinctly harmful, as it frequently leads to any careful attempt to make a non-operative diagnosis being regarded as a waste of time; and, moreover, it sadly depreciates in the minds of the same persons the inestimable value of the education of the eye and hand which is essential for the highly cultured practitioner, and which nothing affords so certain a means of obtaining as the delicate and gentle manipulations which should be inseparably connected with bedside diagnosis. Further, this effect of lowering the standard of bedside diagnosis tends too much, in my opinion, not only to exaggerate the importance of the purely operative aspect of surgery, but to reduce the surgeon to the position of the henchman of the physician, into whose hands the more delicate non-operative diagnosis must, as a matter of course, fall. I am not one of those who think that the present incidence of surgery is to the extermination of the physician—in fact, I believe he will become more and more essential as time goes by. At the same time I am strongly of opinion that it is not the duty of the surgeon to operate at the request of a physician unless he first assures himself that the conditions said to exist are actually present. To do so, it seems to me, is to lose sight of the respect which is due to surgery in the broadest sense. But it is clear that this ideal surgical position is only possible with those who have cultivated to the utmost the power of non-operative diagnosis. The surgeon is in this respect, in my opinion, a physician and something more. Be this as it may, I feel strongly that the performance of the exploratory operation as a mere routine treatment is to be regarded with apprehension, since it tends to the idea that the most careful attempts at arriving at a diagnosis without operation are unnecessary and so conduces to minimising the value of the cultivation of judgment in surgery—a deplorable thing, since judgment is the enemy of routine and routine is the bane of surgery. The exercise of the highest degree of astuteness in diagnosis is, indeed, often necessary before determining upon an exploratory operation. Operations, for example, on the abdomen when the lesion has been in the thorax are not unknown. It is only a short time since that I was called to a case with a view to operating for ruptured gut after a severe injury, in which it was only possible, upon the most careful examination, to determine without operation that the lesion was thoracic and not abdominal, a conclusion which not only negatived the propriety of operating, but probably saved the patient's life, as an abdominal exploration in the degree of collapse which was present must have almost certainly ended in death.

Some Effects of Operations upon Hospital Work; Methods of Operating; and the Attitude of the Public.

The effect of the tendency to regard operations as the main end of surgery has led to a complete change in the course of the last 20 years or thereabouts in the class of cases admitted into the surgical wards of the large hospitals of London, so much so that I believe that I am right in saying that, with the exception of accidents, the admission of patients in the ordinary way whose diseases do not offer a prospect of cure by operation is comparatively uncommon. All possible credit having been allowed to the extensive applicability of the operative treatment, I think that the exclusion of cases unsuitable for operation inflicts a hardship upon many patients and is bad for medical education generally. It would be interesting to know what becomes now of cases which were formerly admitted as a matter of course into the general hospitals, such as early tuberculous disease of joints, diseases of the spine, and many other conditions in which operation is not likely to be called for. It is at all events quite certain that there is no very great opportunity for the study in the surgical wards of the majority of our hospitals of cases which are outside the sphere of probable operation; and I am strongly of opinion that in every hospital a definite number of beds should be set aside for the exclusive benefit of patients suffering from conditions which, whilst curable, are not necessarily so by operation only.

An interesting matter in connexion with the details of operations themselves is the ignorance of the majority of us as to the methods used by other surgeons. This is the result of our seeing little or nothing of each other's work. That this should be so cannot be otherwise than unfortunate, although it is difficult to see the remedy in these times of rush and overwork. I am, however, sure that if we could each of us devote a certain time to watching the way in which operations are conducted by others educated in a different school we should all obtain a wider grasp of methods generally, greatly to the gain of surgery and to our own advantage. As it is, each man learns by experience the method by which he can himself most surely achieve in any given case the desired end; the methods of each surgeon, in fact, gradually become stereotyped which in some instances, unless I am deceived in my impression, leads to some intolerance with regard to the practice of others, since there is an inclination sometimes on the part of a surgeon to regard operations performed by any method other than his own as inefficient or unsuitable, failing to realise, by reason of his insulation, that what he can effect by one plan another operator can do as well, or perhaps better, by some other method. The greatest evil, however, of this condition of things is the fostering of routine operations in consequence of the assumption by some people, because they have no means of checking the view, that for a given condition only one operation is really effective, that being, of course, the *one they are in the habit of using themselves*, a position which rarely if ever bears the test of actual work. In suturing the abdominal wall, for example, there are three main methods, each of which is used exclusively by different surgeons because they have come to think that only one is a perfect plan; yet there have come recently under my notice examples of large ventral herniæ following the use of each of these methods, two examples being in the same patient. Many other instances could, if it were necessary, be quoted.

It is, I believe, safe to say that one of the most remarkable of psychological problems at the present time is the attitude of the public generally towards surgical operations, a problem offering difficulties in its solution second only to those presented by the mystery of radium, for whilst in the majority of instances the dread felt in connexion with the truly necessary operation is so great that it is, I believe, a factor to be reckoned with in deciding upon operations of this kind unless a successful result is practically certain, in cases of expediency and unnecessary operations it is often, unless my experience differs from that of other surgeons, extremely [illegible] altogether [illegible] question of [illegible] cede to a [illegible] r such a [illegible] Whatever the explanation may be there is no doubt that a heavy responsibility falls upon the surgeon in the matter, which is considerably increased by the fact that it indicates such absolute confidence in the integrity of the medical profession. The truth, I suppose, is that the public have an altogether exalted idea of what can really be effected by operation and have only the vaguest idea of what an operation really means. In respect to this attitude it cannot be too fully understood that no amount of anxiety on the part of the person to undergo an operation can absolve the surgeon of one atom of his responsibility in regard to its result—a point which, I fancy, is not always quite sufficiently considered.

A FORECAST AND CONCLUSION.

Nothing that I have already said must be held to mean that I under-estimate the value of operations as such, for no one has a higher appreciation of the immense benefit which is derivable from them and no one can be more ready, or, indeed, more anxious, to employ them in proper circumstances, but I admit that a feeling of apprehension arises in my mind when I regard the inclination which undoubtedly exists at present to consider the operative treatment as the alpha and omega of surgery, an attitude which must not only, as has already been said, end in the reduction of the surgeon to the grade of a mere mechanic, from which he is as far removed as a highly sentient human machine can be from an automaton, but distinctly, in my judgment, stands in the way of progress to better things. It behoves us, and it behoves us well, to bear in mind a fact to which allusion is less frequently made now than formerly—that operations, however perfect in themselves and in their results, are, excepting those rendered necessary by injury and in some cases of deformity and senile change, in truth a reproach to us as a profession, inasmuch as they afford clear evidence of our failure, even at the present time, to obviate the occurrence of the diseases and the conditions which render operation necessary. By allowing the influence of the operative treatment to be too great it seems to me that there is more and more danger of the great importance of preventive measures against disease being lost sight of. In fact, the conception and carrying out of a great operation are liable to conceal the importance of the initial defect which leads to the necessity for its performance. May I give a gross and commonplace example to illustrate clearly what I mean? Cancer of the tongue, setting aside any question as to what may be the factor in the origin of cancer itself, is undoubtedly set alight by one or more of the many irritations, most of them preventable, to which the organ is constantly exposed. But how much time and trouble are taken in preventing these local causes? In other words, how much thought is given to the preventive hygiene of the mouth compared with that which is expended upon the conception of elaborate operative measures for the removal of already existing cancer and upon a consideration of their effective application? The answer will be found to the question by a reference to the ordinary educational works on surgery. Cancer, tubercle, and the results of venereal disease, of which cancer is of course sometimes one, provide a very large proportion of cases requiring operations. The prevention of tubercle or its treatment in the early stages will before long, there is reason to believe, eliminate the necessity for its treatment by operation, and although we at present grope in the dark with regard to cancer, the discovery of the secret of its origin, which is only a matter of time and may come at any moment, perhaps from a least expected quarter, will assuredly lead to its treatment by other means than operation. With increasing sense in the community at large it is to be hoped that an antidote may be found to the sickly sentimentality which stands in the way of the practical extirpation of venereal disease. Apart from these considerations the means for the treatment of disease which tend to reduce the scope of mere operative measures are increasing. Of these the most potent is afforded *by certain of the higher physical* forces, which are slowly but surely encroaching upon the domain which has hitherto been subject solely to the rule of the surgeon. A comprehensive view of the matter generally as it stands justifies, I believe, a forecast that ere many decades have pa[illegible] know him will be a f[illegible] landscape than he now [illegible] restricted degree which I have mentioned, may be looked upon with as little favour as suppuration is regarded by us now. In the meantime, taking things as they are, it is well that we should beware lest a single predominant factor should be allowed to lead to our regarding through a small tube only a subject the horizon of which is absolutely unlimited. It has been said that the basis of surgery is handicraft, and this, *in a sense, is true*; but surely it is a truth only half told, for apart from the issues to which I have referred there is lying behind a far greater thing, the knowledge of when to apply that craftsmanship of which everyone who now aspires to the practice of surgery should make himself a master. Nothing that has happened in the improvements connected with the practice of our art justifies, so far as I know, the modification by one iota of the edict of the great surgeon who, before advancing science had robbed operations of most of their horror, said, "The all-important thing is not the skill with which you use the knife but the judgment with which you discern whether its employment is necessary or not." In other words, those who attach too much importance to mere mechanical dexterity not only fail to reach the high-water mark of greatness but entirely lose sight of the grand possibilities of their calling.

Gentlemen, I have done. Rousseau once said that people are happy in proportion first to their virtue and then to their independence. Being but poorly endowed with the former, such happiness as I have enjoyed has been mainly due to the latter. If, therefore, the spirit of independence has led me to express views to-night with which the feelings of any of those present are not in tune I must crave indulgence upon the ground that my intentions have at least been good.

A Lecture
ON
THE TONGUE IN DISEASE.[1]

Delivered at the Medical Graduates' College and Polyclinic on April 30th, 1903,

By W. HOWSHIP DICKINSON, M.D. Cantab., F.R.C.P. Lond.,

CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN; HONORARY FELLOW OF CAIUS COLLEGE, CAMBRIDGE; CORRESPONDING MEMBER OF THE ACADEMY OF MEDICINE OF NEW YORK.

Gentlemen,—The tongue is a remarkable organ, instructive in a double sense: it not only reveals the mind of man but also his health. As an index of health it may be said to be always truthful, whatever may be the case when it acts as an exponent of thought. My only concern at present is with regard to what we must take to be an accidental or secondary purpose of the tongue as a means of declaring the state of health of the person to whom it belongs.

The tongue has received attention in this respect from the time of Hippocrates until now. A vast amount of experience has accumulated with but little understanding, and until recently little attempt has been made to analyse its teachings or to reduce to their essentials the changes which it presents in disease not proper to itself. Many are the secrets which are incompletely revealed or imperfectly hidden upon its complicated but apparently simple surface. Upon this have been expended much vain imagination and some mischievous dogmatism and with it has been connected much empirical, but not always erroneous, practice. Mysterious sympathy has been supposed to exist between the tongue and the rest of the alimentary canal; as if by looking at one it were possible to discern the state of the other; as if it were the rule for the whole of this channel with its many differences of structure and purpose to share the same pathological state so that a small exposed portion could be taken as a fair sample of the whole. I can remember the time, and it is not quite past yet, when a white tongue was looked upon as a sure sign that "the stomach was out of order" and a dose of calomel or grey powder was inevitable. Such a simple rule is of the greatest service to the practitioner, for it enables him to display himself as a man of prompt discernment and ready execution. It is true that it is erroneous, consistent neither with sound pathology nor sound practice, but it is what may be called a working hypothesis, it points out something *to be done.*

Before a society of medical graduates it would be impertinence to describe the normal state of the tongue; suffice it to say that this is an average, not an absolute, condition and varies much in different individuals. The essential part of the tongue as an index of health is its voluminous and complicated epithelial clothing which may be superabundant, deficient, or partially absent; which may present many varieties of hypertrophy and atrophy; which may be moist or dry, conditions to which great importance attaches; which may expose its own surface however altered by disease, or may, particularly when the tongue is dry, show one which does not properly belong to it but is largely made up of vegetable growths and miscellaneous matters.

Of the morbid conditions of system, or at large, which bring about the alterations of the tongue which are significant of disease the most important is the absence or deficiency of saliva, for this must be regarded as a failure not limited to the salivary glands, but in all probability shared by other of the digestive juices. Boerhaave seems to have seen something of what was little noticed or little expressed by others—the importance of the saliva in relation to health and dryness of the tongue. "The saliva," he says, "continually flows into the mouth of a person in health and nothing is a surer sign to a physician of disease in a patient than his having a dry mouth." Ancient superstition attached mysterious virtues to the spittle.. Without giving it more credit than it deserves we may fairly attribute importance to it as one of the glandular products concerned in digestion which, if any harmony or common consent exist among them, may speak for others beside itself. It is the absence of saliva which, as a rule, occasions dryness of the tongue. Too much weight in this respect has been attached to breathing through the mouth during sleep and otherwise; dryness thus occasioned is incomplete and evanescent. Persistent and considerable dryness of the tongue implies, as a rule, want of saliva; it is this that gives to the dry tongue the clinical importance which belongs to it. The lack of saliva with the dry tongue is familiarly declared by the loss of the power of spitting; the patient has not the wherewithal. He may squeeze out with difficulty a drop or too of thick ill-coloured fluid, perhaps blood-stained, more mucus than anything else, but proper spittle has he none. The same want of saliva is declared by the results of catheterisation of the parotid duct. In health, if a suitable small tube be inserted into this duct where it opens into the mouth, and a little acetic acid be put upon the tongue, saliva will be seen to issue from the gland pretty freely. With the dry tongue little or none, probably none, can be got. Dryness of the tongue therefore indicates lack of saliva; if not in itself a vital deficiency probably a sign of one. I have made a great many observations to this end with the same conclusion—namely, that dryness of the tongue means suppression of saliva. In these observations I am glad to acknowledge the help which I received from my former house physician and present colleague, Dr. Cyril Ogle.

Dryness of the tongue, or in other words suppression of saliva, may, of course, be temporary and unimportant as when the tongue cleaves to the roof of the mouth from mental emotion, but when lasting it implies a grave constitutional failure. Absence of saliva not only produces the various phases of the dry tongue, to which I shall presently advert, but is connected with that very ominous variety of it where the epithelial protection is deficient, the tongue is red and bare, and raw beef a familiar comparison. The lingual epithelium is nourished, as we know, by the blood, not by the saliva; but there is reason to believe that the presence of saliva, by the moisture which it provides, is necessary to its proper growth.

Perhaps the constitutional influence next in importance as telling on the tongue is pyrexia or increased heat of body and breath. We are told by physiologists that cell growth increases with the temperature up to about 104° F. and that it diminishes as it passes this point. The overgrowth of epithelium thus occasioned is the chief, though not the only, agent in coating the tongue in recent and acute disease. Every degree of abnormal heat up to a certain point is indicated, at least in recent and acute disease, by abnormal proliferation and fur. We may regard the mouth as a hot-house for the cultivation of epithelium and the tongue as a thermometer on which every degree of extra heat, up to a certain point, is registered by the coat which it produces. The white tongue of acute febrile disease, which looks as if some white plaster, perhaps white lead, had been spread upon it with care so as to come up to, but not to encroach upon, the edges, is one of the most significant signs of disease which can be presented to the physician.

Another influence bearing on the tongue is a local and even mechanical one, want of friction, scour, and wash, which goes with failure in the process of eating and deficiency of saliva. The part played by want of wear and wash has been exaggerated until it has been presented as the most important of all the agencies which coat the tongue. It will be shown, however, that this plays but a secondary part. The coating of recent and acute disease consists essentially of elongated epithelium, not so much unworn as overgrown, to which adventitious matters add comparatively little. In some forms of chronic disease, however, when under great prostration and suppression of saliva, the mouth probably habitually open, food save in a liquid form impossible, and speech in abeyance, the tongue like old John of Gaunt's, "a stringless instrument"—in such circumstances a vast rubbish-heap may accumulate on this now useless organ consisting of vegetable growths, detached epithelium, débris of food, and accidental matters. This may form a dry crust of extraordinary bulk, not a part of the tongue but a super-addition to it. I have even known such a crust to break off and to look like a cinder, so dry and black and brittle was it.

---

[1] I have dealt with this subject at more length in the Lumleian Lectures, published by Longmans in 1888, entitled "The Tongue as an Indication in Disease."

These influences, want of saliva, pyrexia, and disuse, to which may be added inflammatory or congestive states of the tongue itself such as occur with the strawberry-tongue of scarlet fever and some other conditions, are the chief immediate or direct causes which produce the states of tongue which we recognise as signs of disease. If we were to go behind these and to take account of the remote or indirect causes, the underlying agencies which coat, incrust, and denude the tongue, so numerous and so various should we find them that we should be at a loss to enumerate and to arrange. We should find among them a multitude of disorders, mostly febrile, where some special poison or constitutional infection, either home-made or of foreign manufacture, generally foreign, was recognised or presumed to exist. This would include the specific fevers and many other febrile states which are not so regarded. One obvious intermediary in these cases is pyrexia. There may be a poison in the blood, but this appears to act on the tongue rather indirectly, by way of pyrexia, suppression of saliva, and loss of appetite, than directly. The same intermediaries are concerned in producing the tongue of pneumonia and of other febrile conditions connected with acute inflammation. We should find also many conditions to which such terms are applied as "prostration," "vital failure," and "failure of nutrition," some connected with exhausting discharges and generally, but not invariably, associated with febrile action. All these bring complicated influences to bear upon the tongue—heat, disuse, and lack of saliva; but the greatest of these is lack of saliva.

With this preface I will proceed to sketch in bare and scanty outline the several changes in the tongue which may be called *symptomatic*—the results, that is, of diseases not proper to itself. I shall first refer to the changes in external appearance, taking these as the natural bases of classification. I shall then with the help of the microscope show something of the essential alterations upon which the obvious changes depend and before taking leave of each tongue I shall broadly indicate the constitutional conditions with which it is associated. This brings us to the clinical indications of the tongue, the practical importance of which can scarcely be over-rated. It may, indeed, be said with truth that in many phases of disease the tongue is more significant than anything else which the human economy exposes to view or presents in any way to our senses. It does not point out the site of the disease but it gives a shrewd hint as to its nature; it displays in a comprehensive sum-total its effects upon the system and shows at a glance what the most elaborate examination, otherwise directed, might fail to reveal. The tendency to death which, according to an old saying, it should be our endeavour to obviate may often be discerned by the state of the tongue, which may display upon its surface a request for support and stimulant none the less intelligible because inarticulate. *The tongue often shows at* a glance to the eye of experience whether the patient is approaching health or departing from it; whether he is getting well or going the other way; whether, in short, the coat is [illegible] diminish [illegible] stripping [illegible] whether [illegible] neither. [illegible] he tongue may be traced through successive steps of addition and subtraction. We may follow coat and crust to their maximum of accumulation and then become witnesses of the contrary process until the abnormal covering is removed, much of the normal covering swept away, and even structures beneath the epithelium in part exposed. The first stage of increase or investment, one but little removed from the state of health, is one to which such terms as

DOTTED OR STIPPLED

may be applied. This is characterised by a trifling excess of epithelium on the papillæ either from overgrowth or insufficient removal—not enough to cover the tongue continuously but to besprinkle it with white specks which in the language of small-pox are discrete, not confluent. We see in this condition the first departure from health or it may occur as a matter of personal peculiarity without any. So far as it is morbid it has more to do with disuse than with anything else. It does not bear witness to any constitutional disturbance but rather to its absence, though it may concur with any local disease which has not as yet gravely involved the system. It is necessarily of more serious import when dry than when moist. The average body-heat in 42 cases which displayed this tongue was 98 5°.

THE COATED OR LOADED TONGUE.

The next stage of acquirement is when the intervals between the papillæ are filled up and a continuous coat is presented. This is an exaggeration of the former state chiefly in superabundance of epithelium whether by way of putting too much on or taking too little off, or by both processes combined, as they so often are when pyrexia is associated with want of appetite. The pyrexia stimulates the growth of epithelium, the want of appetite reduces the wear. The white coated tongue, as yet moist, is too well known to need description. It succeeds upon the dotted tongue and is more or less mixed with it, the central part being continuously covered, the sides being only spotted. The intimate changes are chiefly epithelial excess. The processes of the papillæ are elongated; the epithelium of the intervals is superabundant and is probably reinforced by accidental matters. More or less "prostration," to use a somewhat indefinite term, was recognised in a considerable proportion of the instances in which the concomitants of this tongue were recorded and in many the saliva was noticeably deficient. Some degree of febrile action was testified to by an average temperature of 99·1° in 41 cases. Looking at the clinical adjuncts of the moist coated tongue I found that the manner of taking food was often concerned. In 26 of 41 cases the diet was wholly or chiefly liquid, not including two in which it was introduced by the rectum. Apart from diet this tongue concurred with a variety of conditions too numerous to mention where in general terms the patient was ill but not very ill. A [illegible] hich it is apt to occur would [illegible] humanity and many of the [illegible] f long continuance. Whatever raises the temperature, impairs the appetite, or restricts the salivary wash may give rise to this state of tongue to lead, it may be, to more ominous phases. I need not insist on what is almost obvious, that when the coated tongue is dry the indication is more grave than when it is moist and [illegible] 18 cases gave an [illegible] deserve especial mention, the "strawberry tongue" and what I have ventured to call the "plastered tongue." With the strawberry tongue injection underlies the coating through which the red papillæ project, *the converse of what holds with the fruit* where the white projections push through a coloured ground. The ideal strawberry state occurs with scarlet fever where the tongue appears to participate in the eruption; but lesser degrees of it are to be found in other febrile conditions. What I have called the "plastered tongue," which looks as if white lead or some less vividly white and coarser grained material, more like mortar, had been carefully spread upon it, abruptly ceasing at the edges, is the acute coated tongue or the coated tongue of acute disease. The coat is more white and more sharply defined and the substratum is more red than with the coated tongue of trivial or chronic disease. The fresh look of the coat betokens recency and its abundance the activity of the process which has produced so much in so short a time; in other words, the acuteness of the disease with which it is associated. The minute anatomy of the plastered tongue is that of the common coated tongue, only more so. The elongation of the papillæ is greater; there are more filling up of the intervals and more accumulation upon the summits of miscellaneous matters—epithelial, parasitic, and accidental. There is no tongue more instructive and distinctive. The first glance gives the alarm and suggests pneumonia or typhoid fever in the first place, then acute bronchitis or acute rheumatism. Nor are other acute febrile disorders to be ignored, though less to the front than those which have been mentioned. The average temperature of 27 persons presenting this tongue was found to be 101·6°.

Turning from the acute coated tongue, the most definite in its indications of all the tongues we know of, we come to one which is less distinctive, more often chronic than acute, signifying disuse more than anything else. This may be called

THE FURRED OR SHAGGY TONGUE

and is charcterised by the preposterous length of the papillæ suggestive of coarse and matted fur. The word "fur" is used in two senses—there is the fur of a beast and the fur of a tea-kettle; the one presents a series of points, the other a level surface. The word has been applied to the tongue in both senses, perhaps the more often as implying a smooth coat. I have, to avoid confusion, restricted it to the animal usage—beset with points. The elongation of the papillæ is evident to the naked eye and during life. They are often tipped with brown and more or less obscured by incrustation and may present irregular pointed masses. I have seen in a case of cancer of the larynx much of the hinder region covered with a villous production like coarse hair, no part of the cancer, but only an exaggeration of the natural structure condemned to disuse. Under the microscope the chief change is elongation of the filiform papillæ, more especially of their extremities, which in a microscopic sense may be termed horny, yellow, and rejective of carmine. The circumstances of this tongue are for the most part restriction of diet and want of wear and of saliva. Of 29 cases where this variety of tongue was noted were 21 where ordinary food was absent or restricted, 17 were on liquid diet, three were on dry diet, and one was on rectal diet. Except with diet this tongue has no special association, though some degree of pyrexia is usually present and helps to stimulate the growth of the papillæ. 22 cases of the furred and dry tongue gave an average temperature of 99·1°. This tongue is usually dry and when so promises ill. It occurs more often with chronic disease than acute, though I have noted among its associates pneumonia, typhoid fever, and acute rheumatism. It generally tells of long illness (for the exaggeration of the papillæ is a slow process) of such a sort as to restrain the saliva and to inhibit solid food.

Succeeding upon the plastered and furred tongue comes that which is

INCRUSTED, BROWN, AND DRY.

The elongated papillæ are there but they are separated and caked over with a brittle crust, variously cracked and fissured, which largely consists of vegetable organisms, oidium albicans and micrococci, together with detached epithelium and extraneous and miscellaneous matters. This is the climax of acquisition. It tells of long exemption from wear and wash, of absence of mastication, suppression of saliva, and generally, though not necessarily, the presence of a high temperature. This is the tongue of the "typhoid state," though by no means limited to typhoid fever. It is of grave prognosis and calls for liquid nourishment, of which alcohol forms a part. This is the tongue of long-continued prostration or failing vitality; the essential factor is long suppression of saliva; pyrexia is generally present, though not necessarily so, since it is possible that the tongue may be dry and incrusted, though the temperature is subnormal. Typhus and typhoid fever, pneumonia, and pyæmia are frequent concomitants. To name all the conditions with which it may concur would be to include many, perhaps most, depressing and exhausting diseases, especially such as are nearing their fatal close. A dry mouth, failure of the salivary and probably of other glands essential to nutrition, the absence of the power of taking other than liquid food, and probably withal a febrile temperature—these are implied by the incrusted tongue and together are of evil omen. The average temperature of 21 cases of this tongue was 100·3°.

Having traced the coating of the tongue through its various stages up to its maximum in a cindery addition, perhaps an eighth of an inch thick, we now come to the contrary process, that of denudation, which ends in the tongue which is

RED, SMOOTH, AND DRY.

This, naked, bare, and raw-looking, so as to be likened in common parlance to beef-steak, is produced in this wise. After the continuance of some wasting or depressing disease, often attended with exhausting discharge, it may be of pus, the lingual epithelium fails to grow properly; the upper layer disappears and the deeper is laid bare; or even in parts the whole epithelial thickness may go leaving the deeper structures exposed to the irritating contents of the mouth. Connected with the general exhaustion or depression is the consequent deficiency of saliva which when long continued seems to impair the nutrition of the epithelium—not that the epithelium is fed by the saliva, but it needs to be kept moist to profit by its opportunities. The denudation may succeed by a gradual process upon health, as this gives way to disease, or it may ensue upon the incrusted tongue, the crust breaking off or wearing away. The upper layers are often swept away down to the Malpighian, or this may go too, laying bare the corium which becomes injected and charged with leucocytes. Often a process of repair may be discerned. The deep remains of the epithelial layer, the papillary prominences being swept away and the tongue levelled, now become clothed with a delicate translucent membrane of uniform thickness, barely evident except with the microscope, which scarcely interferes with the raw beef appearance. This membrane refuses carmine and is apparently representative of the superficial epithelium which normally tips the papillæ.

Like the incrusted tongue, that which is raw and red is associated with pyrexia as a general though not an invariable accompaniment and with deficiency of saliva probably as an invariable one. But there must be other and special circumstances which determine that the tongue shall be denuded rather than incrusted or furred. It appears, in the first place, that the denuded tongue represents a later phase of disease than the coated or incrusted, for it often succeeds upon these and takes longer to make. To what extent want of saliva alone is able to make bare the tongue may be doubted. The circumstances in which it becomes so suggest that though suppression of saliva may be contributory, some special cause of exhaustion, often by discharge, is also contributory.[2] I have elsewhere quoted a case in which after a nervous shock the saliva was permanently suppressed and the tongue became not only dry but red and bare. It is possible that there may have been more in this case than we know of. At any rate, it is clear that exhaustion by discharge plays a large part in the impairment of nutrition which this tongue represents. Among 30 cases in which it was observed were five of diabetes, four of phthisis or other forms of tuberculosis, two of lardaceous disease, two of dysentery and abscess of the liver, and four of purulent discharge in some other shape—17 in all in which a morbid flux concurred with the tongue under consideration. The most vivid example of this tongue which I ever chanced to light upon was in a case of dysentery with unopened hepatic abscess. Pyrexia does not range so high as with some of the preceding types of tongue, giving for 29 cases an average of 99·6°. The diseases with which it is associated are mostly subacute and the fever is often hectic. Thus, the clinical significance of the red bare tongue is clear enough: prostration of some standing, often connected with material exhaustion, and apt to be attended with febrile action of the hectic type. The salivary secretion is deficient though not so much so as with dry incrustation. Physiologically the essential factor is failure in the growth of the lingual epithelium, apparently due to a concurrence of causes rather than to one alone. Whether apart from its action by way of the saliva the constitutional depression has any direct effect in inhibiting epithelial growth must be asked—it looks as if it had. All the processes of nutrition must be supposed to suffer where there is a cause of exhaustion which acts on the whole body, but if the denudation of the tongue is wholly due to this cause nowhere else is the impairment shown so conspicuously as in the lingual epithelium.

Of this organ I have now traced the morbid covering from mere dotting of the papillæ to its climax in mountainous accumulation and have then followed the reverse process by which the tongue has been stripped of its coat and even of its skin. I have pointed to some, perhaps the chief, of the agencies at work in bringing about these changes: the abeyance of food and friction, the deficiency or absence of saliva, and the association of pyrexia with overgrowth of epithelium, and of some forms of exhaustion with its falling away. I have shown that the tongue, whatever else it may be, is a constitutional index or systemic gauge which comprehends much and reveals much, and is especially in touch with conditions of fever. It does not point out the locality of disease but it shows its general effects, often hints at its nature, and offers some broad hints as to its treatment. Nor must I omit to recall what I have already hinted at—the prognostic value of the organ in question. If "old experience doth attain to something like prophetic strain," it is often by means of the tongue that this gift is manifested. Invaluable is the quick assurance in a case of acute disease that the patient is on the road to recovery which is imparted by the first glance which shows the coat to be withdrawing regularly round the edges, exposing a wet and healthy surface. If the tongue is on the mend so must be the man. Quite otherwise is the prospect afforded by an irregular breaking away of the coat, giving to view a substratum which is red and wanting in moisture.

---

[2] The Tongue as an Indication of Disease, Dickinson, p. 83.

I cannot flatter myself that what I have this day put forward, drawn partly from the common stock of medical knowledge and partly from my own observation, is anything more than a very imperfect attempt to connect the morbid [illegible] with the disturbances of health [illegible] Though the subject in some of [illegible] most ancient in medicine, yet in others it dates no further back than the microscope and thermometer and in all but what is empirical is in a provisional stage. But if we do not know all we know enough to be sure that the value of the tongue in clinical medicine deserves a fuller exposition than it has this day received and a more able exponent.

An Address

ON

THE DISPOSAL OF THE WOUNDED IN NAVAL WARFARE.

Delivered at the Royal United Service Institution, Whitehall, on May 12th, 1903,

By PHILIP N. RANDALL, M.B. LOND.,

LATE SURGEON, R N.

GENTLEMEN,—Naval medical officers view with foreboding and dismay the prospect of being called upon to deal with a large number of serious injuries in such situations and under such conditions as are unsuited for such purposes. The sick-berth of the present day in the navy has gained light and air but the situation selected for it in all modern ships is thoroughly recognised to be one which would be absolutely untenable in actual warfare. The period of convalescence is one which at all times calls for constant and anxious attention but more particularly after major operations performed upon those who at the time of their injury sustained in consequence a profound shock to the whole system. Shock, *per se*, adds greatly to the difficulties present and the dangers to be apprehended in every case. There must be a provision of such prime hygienic necessities as space, light, fresh air, warmth, comfort, and complete freedom from all septic dangers. In considering the means at present existing in ships for the accommodation of the wounded the first point which seems most naturally to offer itself for attention is the position and capacity of the sick-bay provided in each ship, seeing that this is the only place in the ship devoted to, arranged, and fitted out for the work of the medical staff. However, in all modern ships it has been found necessary to seek for a cock-pit for use in action, and a site is officially selected for such use. It is this place, therefore, that must needs be considered and not the sick-berth. A return to the cock-pit principle has been decided upon officially for some time past but beyond the selection of a site nothing further has been done to make the place selected in any way fit for its important duties except the provision of an operating-table. The question of the accessibility of the cock-pit from the fighting decks raises a practical difficulty which has always been present and has become increasingly harder to compass in each new type. The features that so complicate the matter are due to the introduction and the more and more extensive use of water-tight compartments with a corresponding increase in the number of the divisions and subdivisions of a ship by means of watertight bulkheads. The use of armoured decks introduces a still further interposition of difficulties. When the ship is cleared for action every opening in all these transverse, longitudinal, and horizontal partitions is necessarily closed up, only such as form the means of communication between the magazines and the fighting stations being left open. Conveying the wounded to a dressing station improvised below the armoured deck has therefore become a matter of considerable difficulty, for the choice of position for such work is not only limited by special needs as to size of aperture necessary but also by the finding of a hatch that can possibly be used for the purpose. A torpedo hatch is usually selected as having sufficient size and probable freedom from other uses. When the wounded have been brought down through a hatch to the flats, there still remains the necessity of finding a suitable place for their bestowing; but whether it be the barbette flats, the wing passages, or the bathrooms for the engine-room ratings, the same serious objections apply to all. In not one of them is there any supply of air or light, other than by artificial means. The boilers and engine-rooms are in close proximity, keeping the places at a high temperature and rendering the air close and stuffy even under the ordinary conditions of cruising when all the boilers are not in use and every possible opening is kept free. Tightly closed down in action, with all the boilers alight, would mean a very considerable aggravation of already objectionable conditions It might, perhaps, be possible to accommodate about 40 cases in these flats but to do so they must be laid on the deck and packed closely together.

The next point to be considered is the state of things that would actually obtain and have to be dealt with during and after an action. In other words it is necessary to determine as approximately as possible the number of wounded *that would have to be dealt with as the result of* an engagement. There are strong grounds for the belief that, in an action in which there are highly trained and [illegible] side, the number of [illegible] that obtaining in the [illegible] now be concentrated upon the hulls and not upon masts and sails, which latter were the primary object of our former foes. A working average of 7 per cent. of the complement, as the number of wounded to be expected in each ship in action, cannot be said to err on the score of exaggeration, but must rather be looked upon as the irreducible minimum. If that figure be taken as a working average, and applied to battleships, &c., now composing our main fleets, and certain to be actively engaged in a naval war, an approximate number may be obtained of the wounded that would have to be treated in each ship that emerged from the contest. At the same time it must be borne in mind that this approximation may only represent a third, or even a fourth, of what might actually occur. The total wounded for the Mediterranean fleet would be 1112, the total wounded from the Channel and Reserve F[illegible] the China Fl[illegible] at an estim[illegible] be expected the condition of the ship itself after an action may be considered. The unarmoured parts would be completely riddled by every sort of projectile, shot, shell, and bullet, so that the internal arrangements of those parts would be in a state of complete and thorough disorganisation, due not only to the wreckage and destruction wrought by the explosion of shell but also to the consequent outbreaks of fire; as regards the armoured parts of the ship it is at least doubtful whether the best protection yet devised would remain intact, so that at any rate there can be no doubt about what would happen to parts where there was a less amount of protection by armour, whether in thickness or in quality of face. It is, in fact, laid down by more than one authority that, to escape as much as possible [illegible] shell, it is better [illegible] easily pierceable [illegible] would therefore be found within the armoured parts as without, though maybe not to the same degree of destruction. We are now able to consider how far the means at present provided would go to meet the demands that would actually be made upon them. It will enable matters to be seen more clearly if the facts, as established, are actually applied to a ship like the *Majestic*, as fairly representing the modern type of battle ship. The *Majestic* has a complement of 757.

The cock-pit would be established in the lower deck flats, below the armoured deck and inside the protected part of the ship. Either the barbette flats, the wash-places, or the ammunition passages would be selected. The sole means of communication between such places and the fighting decks would be devious and difficult; the only provision of light would be by artificial means and probably only by candles; while all means of ventilation would be cut off by the closing of the armoured deck and the many bulkheads that exist. This last measure would be a vital necessity for the ship, but would make many times worse an atmosphere which under ordinary conditions is close, mephitic, and kept at a high temperature by the proximity of the boilers, all of which are in use. The vitiation of the atmosphere of a closed space increases rapidly with each expiration from the lungs made by every person present therein and each addition to the number of persons adds to the foul and poisonous condition. The number of wounded to be expected, according to the average, would not be less than 53. When the ship emerges from action with her unarmoured ends completely wrecked and disorganised, with her armoured parts in a somewhat similar condition, with numerous shot holes and rents in her sides allowing seas to wash in freely so that the decks and flats about the level of the water-line would be flooded with water, with, perchance, injuries from ramming or torpedo which by alteration of stability or damages to engines and other vital parts would only add to the general confusion, and with lighting and ventilating arrangements probably altogether unworkable and completely broken down, how and where, it may be asked, will it be possible to find a place wherein at least 53 men with, in the majority of instances, severe wounds can receive in even the least degree that immediate care and attention, and especially the fitting after-treatment, which are necessary to save their lives? The attempt to accomodate them in the flats could, and would, only mean a return to the disastrous effects of earlier days. The teaching of former experience has been writ large in naval, military, and civil practice, and the meaning of the writing on the wall cannot nowadays be possibly misunderstood or misconstrued. Consequences of terribly fatal effect would most certainly be entailed if, and whenever, 50 men—or for that matter half a dozen men—were closely packed together on the wet deck of a heated, stuffy place, never visited by daylight, having no natural supply of pure air, and with the artificial supply of both most probably cut off. They would have to breathe an atmosphere thickly charged with respiratory products and human emanations. The blood about the deck, the clothing, the bedding, and dressings would speedily become putrescent, and there would soon be poured forth from the large wounds a vast amount of putrescible discharge. In a medium so favourable to the production and rapid growth of many kinds of infective bacteria, erysipelas, tetanus, hospital gangrene, and all the fell products of septic infection would inevitably be developed, while all means would be powerless to avert their ravages and they would deal death far and wide among all cases of wounds, whether these were of large or insignificant dimensions.

Demonstration has now been made that the number of wounded would be large in every ship actively engaged; that the accommodation at present provided in ships would be insufficient for even a fourth of the number that might be expected; that this accommodation, being in the unarmoured part of the ship, would be impracticable for use during action; that it would be absolutely unfit for any use whatever afterwards; that it would be impossible to obtain elsewhere in the ship adequate and proper accommodation for the wounded; that the suggested cock-pits are in no wise suitable in size or in general conditions; that the use of so insanitary a place would infallibly bring about outbreaks of septic diseases of the most virulent kind; that no means of transport would be found on board available for use after action; and that the only hospitals large enough to receive the numbers consequent on a fleet action are at Portsmouth and Plymouth. The evidence thus adduced and set forth can lead, after careful consideration, to but one conclusion—that in the fighting line afloat, as in the case in that ashore, all treatment of the wounded beyond "first aid" would be impracticable, and further, that after-treatment on board would, in justice to the wounded, be a practical impossibility. There is, however, an obvious way out of the *impasse*, which is the adoption of the principle of hospital ships for fleets, thus ensuring the saving of many lives which would otherwise be certainly wasted. Every fleet of battleships should therefore have attached to it one or more ships entirely devoted to, and specially fitted out for, hospital duties, flying the Geneva Cross, and complying in all respects with the terms of the Geneva Convention and those of the Hague Conference. These fleet hospitals would cruise with the fleets, and, having first received all cases of serious illness from the ships, would accompany them to the verge of safety when they went into action. Each hospital ship should be provided with as many large and roomy boats as could possibly be carried. By means of these boats endeavours could be made to maintain close communication with the fighting line, seizing upon every opportunity that offered, such as a ship hauling out of action, to collect and to transfer to the hospital ship as many wounded as possible. This may or may not be practicable, but the main use will be when the action is over. The hospitals would then close with the fleet and their boats would bring away all the wounded from every ship in the fleet. By these means the ships of the line would be freed from the encumbrance and hampering due to the presence of wounded on board and would be left with crews necessarily diminished in numbers but composed of those fit and able to devote their whole attention to their own proper duties. The benefits accruing to the wounded would be incalculable, for once received on board the hospital ship their treatment could be carried out each and every case in proper detail and according to needs, quite free from difficulties which otherwise would be overwhelming. At the same time excellent conditions for the due and proper after-treatment of the cases would be completely insured. The movements of the hospital ship subsequently to the action would necessarily be governed by circumstances, but whether despatched to the nearest available hospital or remaining at sea with the fleet those on board would be under conditions offering the best means of recovery and vastly different to a labouring and probably long-drawn-out voyage in a much damaged battle-ship possibly unable to effect more than a few knots of speed.

Under these conditions the services of the medical staff would have to be disposed in three ways—in the fighting line, in the collecting boats, and in the hospital ships. In the fighting line only "first aid" should be rendered to the wounded and for this purpose dressing stations should be established where possible and convenient. One medical officer in each ship would be sufficient for the supervision of that work and his sick-berth staff should be reinforced by the chaplain and accountant staff, for all of whom thorough instruction and examination in those duties should be made compulsory. The medical officer and his staff of assistants must be free to move about the ship as expeditiously as they can and to go wherever they are most urgently needed, as, for instance, to a case-mate wrecked by a shell. A central dressing station would naturally be of the greatest assistance but it must be regretfully admitted that very little can be hoped for in this direction in view of the very complicated arrangements of modern ships of war. The introduction and general use of case-mates for the guns of the secondary battery suggest that these might in some way act as a screen for dressing stations established in rear of them. The deck would be clear, communication would be easy, and the wounded would be most conveniently placed for removal to boats whenever a suitable opportunity presented itself. The difficulty of conveying the wounded would thus be completely avoided and there would be a great gain in promptitude of attention by the medical staff. The collecting boats should be steamboats of good and handy sea qualities, as large and roomy as possible, and accommodating six or eight cases. They must be manned by crews well skilled in boat work, as well as in the hoisting in and out of cot cases. Not less than 12 of these boats should be carried by each hospital ship.

The type of ship most appropriate for the purpose of a hospital ship is one on the general plan of a modern mail steamer of the best class, of good size, and capable of maintaining a continuous sea speed of not less than from 18 to 20 knots so as to keep station with a modern fleet proceeding at full speed. The wards should occupy the centre and forward parts of the ship, where nowadays is placed the first-class accommodation in mail steamers, thus insuring a liberal supply of fresh air, light, and deck space. It would be well to limit the accommodation of each ship to 500 cases, so as not to involve too large a staff and consequent difficulties in finding sufficient room for their due requirements and convenience. The ships should be specially built for the purpose and not adapted from existing mail steamers, so as to insure complete protection from septic dangers *Mutatis mutandis*, all the details, large and minute, now introduced into modern hospitals with the object of limiting as far as possible resting places for dirt of every description should be carried out in the ships so as to obtain damp- and germ-proof floors, walls, and fittings throughout In a word, the hospital afloat must be built in every respect in accordance with the principles adopted in the hospital ashore and must be as perfectly self contained in every respect

With a ship thus equipped for the purposes of active service, and by strict attention to all other details besides those briefly alluded to which insure complete asepsis, it will be possible to remove completely the stigma which formerly attached to hospital ships which had been used in connexion with military operations from a sea board base The wounded would be able to do as well as if treated in well appointed hospitals on shore, moreover, they would not be taking up room which, if found, could be ill-spared and would be wholly unsuitable, they would not be in the midst of extremely insanitary conditions which would cause them great distress and be of actual deadly effect, they would no longer be exposed in a helpless and hopeless *position to fresh wounds in any further action*, but they would have every possible means known to modern science afforded them of remaining to prove of further use to themselves and to their country A profitable use could be found for such ships in time of peace Part of the year could be devoted to cruising with their respective fleets, carrying out manœuvres which should embrace all the details for active service, thereby insuring proper training and efficiency For the remainder of the year they could be used for the conveyance home of invalids only from India and other foreign stations at the cost and charges of the respective military authorities A special service in this respect would be a great boon to all concerned and has long been needed

THE SURGICAL TREATMENT OF PULMONARY HYDATIDS

By JOHN O'CONOR, M A, M D T C D,
SENIOR MEDICAL OFFICER BRITISH HOSPITAL BUENOS AYRES

As little or no mention is made in English text books as to the prevalence of hydatid disease in the Argentine I should like to draw attention to the frequency of the affection there, for I think that if reliable statistics could be procured in all probability it would rank as second to Australia in this respect During the past eight years I have operated on 84 cases, 56 of which were hepatic and only three pulmonary Obviously the experience derived from a few cases affords little material for conclusions, yet as hydatid of the lung is comparatively rare possibly the notes of my cases and the details of treatment may be of some interest.

I cannot help thinking that two of my patients would have succumbed if operative treatment had not been adopted, and in making this statement I am cognisant of a recent contribution by M Dieulafoy in which he arrived at this somewhat disconcerting conclusion "The treatment is more or less expectant, being directed towards the control of the hæmoptysis, surgical intervention can seldom be of much use, for when the cyst empties itself there is no need to interfere and in other cases their localisation may be too difficult to warrant exploration" By way of comparison the following extract from Mr Stephen Paget's work on "The Surgery of the Chest" is most interesting "It is plain that the mortality of hydatid disease of the lung left to itself is somewhere between 50 and 60 per cent, to say nothing of the years of illness which some of these patients undergo Statistics of operation are in strong contrast with those of non interference In 1885 Thomas collected 32 cases of hydatid of lung treated by free incision with no less than 25 recoveries—he puts the mortality left to itself at 54 per cent

The rupture of the cyst into a bronchus may of itself be a frightful ordeal even if it does not end in death" Con

sid

ha

the

of

The important primary points connected with a case of this sort are diagnosis and localisation The former may be attended with much difficulty, for if the cyst has not ruptured into a bronchus microscopical examination of the sputum, which is our one positive diagnostic resort, affords only negative information In such instances the family and personal history of the patient have carefully to be considered and also the locality in which he has resided for previous years, *as in countries where hydatid disease* is common one has always to eliminate the echinococcus before definitely deciding as to the nature of any tumour The unilateral situation of the affection with probably a sharply defined dull area not corresponding to the usual site of a pleural effusion or hepatic enlargement, taken in conjunction with diminished breath sounds, vocal and tactile fremitus, with antecedent evidence of an irritating hacking cough with bronchitic sputum, may reasonably excite one's suspicion

If rupture of the cyst has occurred the symptoms may be altogether different There is usually the history of a sudden evacuation of a quantity of fluid, followed by frequent, and at times considerable, hæmoptysis—a complication which not only seriously aggravates the condition of affairs but also affords evidence that a communication exists through which air can pass into the cyst cavity, the result being *that* the *latter* becomes gradually converted into an

diagnosis in this phase would be almost impossible if it were not for the fact that microscopical examination of the sputum now affords positive evidence—viz., hooklets and bits of necrotic chitinous material The latter may be often detected without the aid of a microscope and are commonly described as pieces of "gooseberry skin"

It may be expedient to remember that the absence of any of the usual symptoms does not negative the presence of a cyst, for diminution of breath sounds and existence of dulness are to a great extent determined by the amount of lung tissue which intervenes between cyst and chest wall and *it is obvious that there must be a period in the development* of all "intra" pulmonary hydatids in which physical examination would not reveal anything abnormal And it is only when the cyst assumes such proportions as to cause irritation of the lung that the first symptoms, dull pain and cough, supervene So much have I been impressed with these subjective symptoms as being indicative of hydatid that I usually assume the presence of hydatids on hearing a healthy looking camp man complain of a pain over the right hypochondrium (liver) or of a hacking cough with or without pain in the chest If physical examination does not afford a clue I usually adopt a waiting policy and advise the patient to return to work and to report himself periodically if things do not improve Quite a number of these patients return in from six months to two years with a "full blown" cyst As hydatid disease is fortunately a lazy one I think we *may profit* by the fact and adopt the business man's tactics, await instructions, which in this instance signify a few physical signs which ordinarily denote the existence of disease But, as I mentioned above, it is impossible to diagnose with certainty a case of pulmonary hydatid in which rupture into a bronchus has not occurred, even admitting the existence of well defined dulness, diminished expansion, &c., consequently if we suspect hydatid and are prepared to deal with it surgically I see no help for it but to fall back on some exploratory device

Personally I do not much fancy opening the chest on an exploratory mission, for not only does thoracotomy in itself entail risk to the patient but it by no means follows that such an opening would correspond to the most suitable point at which to attack the cyst, moreover, it must be remembered that in many cases the capsule may not be evident even when the lung is exposed (*vide* my cases) Consequently I not only recommend the employment of the exploratory syringe and needle as a diagnostic agent but as a valuable aid to localisation, by the information thus derived we are enabled to plan our incision so as to correspond with the most superficial portion of the cyst and so avoid unnecessary interference with lung tissue While advocating the use of the needle I ought to mention that in two hepatic cases rather alarming transitory toxæmia followed an exploratory puncture, I now make it a rule to perform such exploration under anæsthesia on the operating table and immediately to back up the needle by a scalpel if hydatid fluid is struck. By this means I think that any danger attending the escape of hydatid material into a serous cavity may be practically eliminated.

As I do not know of any operation in which it is more necessary to commence with a definite plan of campaign I may be pardoned if I enter rather fully into detail. Chloroform having been administered, the patient is placed in the supine position, with the affected side well overlapping the edge of the operating-table and two assistants are deputed to maintain this position throughout. On removal of the perchloride lint dressing an assistant washes the whole side of the chest with alcoholic acid mercurial solution (1 in 1000). An exploring needle is next inserted into the suspected area and if fluid enters into the syringe the latter is detached and the needle is utilised as a sound to locate the most superficial portion of the cyst. Once this point is decided on the needle is withdrawn and a four-inch incision is made parallel to the corresponding ribs, a few inches of the latter are resected, the pleura is opened and the presenting lung is instantly secured by two good bullet forceps and rapidly drawn into the wound. By this manœuvre the confusing storm consequent on a collapsed lung is obviated and blood and hydatid fluid are later prevented from dropping into the pleural chasm and setting up a septic pleuritis which not infrequently proves fatal. The bullet forceps are then handed to an assistant whose sole duty it is to take care that this extemporised cork does not slip back. The exploring needle is again inserted and if fluid appears in the syringe the latter is removed and the needle is left *in situ* so as to act as a guide for the knife which is now entered alongside it. The intervening lung tissue is incised and the cut edges are seized by forceps and everted. The knife is then pushed into the cyst and as the fluid escapes the exploring needle is withdrawn and the left index finger is introduced along the blade of the knife into the cyst; the latter is in turn removed, two sharp hooks are inserted alongside the finger, and by this means the cyst wall is secured and drawn outwards. With a large full-curved needle some half a dozen silkworm gut sutures are applied so as to include the cut edges of the fibro-cyst with some pulmonary tissue and passed outwards through the intercostal muscles and the skin and just as they are being tied the assistant removes the bullet forceps so that the extruding portion of lung may recede. With this the operation is practically concluded; the endocyst is removed by gentle application of a long forceps, a large rubber drain is inserted, and iodoform gauze is applied to the wound.

The after-treatment is most tedious as there is a great tendency to the formation of a flask-shaped cavity—viz., closure of the external wound before the cavity in the lung is obliterated. I have frequently observed the same in hepatic cases and on six occasions I have been compelled to make an intercostal counter-opening subsequently to cœlio-hepatotomy.

There are some who, notwithstanding the experience derived from Bond's operation in liver cysts, still advocate removal of the contents of the fibro-cyst and closure of the external wound without drainage. In suppurative cases such treatment would be obviously inane and even in non-suppurative cases, considering that the fibrous sac has to be got rid of somehow, I cannot see any reason for not availing ourselves of a ready exit without taxing nature with its absorption, not to mention the possibility of the cavity becoming septic after operation. I tried Bond's method once in a case of simple hydatid of the liver and 14 days later I had to re-open the abdomen in order to clear out a large quantity of pus; fortunately, adhesions had formed between the cyst and the parietal peritoneum or the result most probably would have been disastrous.

CASE 1.—A man, aged 51 years, was sent into the British Hospital, Buenos Ayres, on Dec 24th, 1896, by my friend, Dr. L. Colborne. About 12 months before admission he first complained of a dull pain in the right chest, which was soon followed by an irritating cough with a small quantity of clear sputum. Three months previously he had suddenly coughed up a large quantity of blood-stained liquid; severe attacks of hæmoptysis ensued, accompanied by nocturnal fever, sweating, shivering, and loss of flesh. There was nothing in the personal or family history which threw any light on the subject. Physical examination revealed absence of respiratory movement on the right side, with marked dulness over the anterior and lateral portions; respiratory sounds were absent and vocal and tactile fremitus were considerably diminished. On the evening of his admission into the hospital his temperature was 102° F., his pulse was 110, and his respirations were 35, and he was continually coughing up blood. The existence of a resonant patch beneath the angle of the scapula, with free entry of air, struck us as somewhat suspicious, so an exploring needle was inserted and some clear watery fluid appeared in the syringe (it contained hooklets). On the following day chloroform was administered and, assisted by Dr. Colborne, I excised three inches of the fourth rib in the anterior axillary line. Lung tissue presented and had to be incised for one inch in depth before we encountered a large cyst which contained nearly two pints of clear fluid, about eight ounces of pus, and a necrotic endocyst. The operation as described above was carried out and the patient was discharged cured on Jan. 22nd, 1897.

CASE 2.—A youth, aged 18 years, entered the hospital on May 4th, 1901, with the diagnosis of hydatid of the lung. In April, 1900, he first complained of getting out of breath on slight exertion and a few months later a troublesome cough supervened, with abundant frothy expectoration. He gradually lost flesh and occasionally felt feverish, and as physical signs of some lung affection became obvious in November his medical attendant determined to explore. Curious to relate, while the syringe and needle were being disinfected in the patient's bedroom he was seized with a severe paroxysm of coughing and brought up about "two litres" of "water." This seemed to relieve matters for a time. In January, 1901, the cough became very persistent, with frequent hemoptysis; fever, sweating, chills, and loss of appetite became intensified and in February he coughed up "bits of skin." On his admission into the hospital physical examination of the right chest revealed diminished expansion and marked dulness from the third rib downwards in the nipple and axillary lines and abundant bronchial râles, with some moist sounds, were elicited on auscultation over the dull area. Posteriorly the percussion note was modified and some vesicular breathing was heard in the scapular line. Tactile and vocal fremitus were increased over the affected area The evening temperature was 101° F., the pulse was 90, and the respirations were 32. During examination he coughed up two pieces of cyst. Operation was performed on May 10th. Half an inch of lung tissue intervened between the chest wall and the cyst which was attacked through an incision over the fourth rib in the anterior axillary line. About a pint of pus and a gangrenous endocyst were removed. A most protracted and tedious convalescence ensued, the wound discharged for months, and he could not be sent out as cured until August 19th.

CASE 3.—A boy, aged six years, was admitted into the hospital on Oct. 9th, 1900, with the following history. His mother stated that in April "he caught a severe cold" and a short dry cough remained which, in spite of a month's sojourn on the Cordoba Hills, had continued up to the date of his admission. After some time it was noticed that he was getting thinner and losing his appetite and a nocturnal rise of temperature was noted without any sweating or shivering. On the morning of his admission the temperature was 101·6° F., the pulse was 120, and the respirations were 40. The patient appeared to be somewhat emaciated; he had flushed cheeks, dry and hot skin, and a furred tongue. On examination of the chest there was distinct subclavicular flattening with diminished expansion over the right apex, resonance was deficient anteriorly and posteriorly, tactile fremitus was decreased, and there were harsh tubular breathing and twanging voice sounds. The breath sounds were normal over the rest of the lung. There was no history of tuberculosis in the family but an elder brother had suffered from hydatid of the liver. The evening temperature reached 103·6° F. There was a most troublesome cough with a little bronchitic sputum. On Oct. 11th chloroform was administered and a needle was inserted into the second space in the nipple line and some purulent fluid was withdrawn. Judging from the depth at which fluid was struck it was evident that the cyst was situated in the posterior portion of the apex. An incision three inches in length was made parallel to the second rib commencing in the mid-axillary line and extending backwards to the margin of the scapula. A few inches of rib were excised and owing to adhesions with the posterior wall it was found impossible to draw the lung into the wound, the lung collapsed, considerable shock immediately ensued, and to make matters worse six punctures with the exploring needle failed to locate the cyst. The anæsthetist at this stage of the procedure mentioned that "things are looking blue" and as there was no time to lose I pushed a knife upwards and backwards into the adherent apex and the sense of relief can be better imagined than described when I saw fluid flowing out along the blade of the knife. A forceps was inserted alongside the latter and the opening was dilated so as to admit a finger, which detected a small collapsed cyst with only a few tablespoonfuls of pus. The cyst was removed and a large rubber drain was inserted into the cavity and another into the depth of the pleural chasm The child's condition continued most grave for two days but youth, warm nutrient enemas, and strychnine saved the situation and after a sharp attack of purulent pleuritis the patient was discharged cured on Nov. 30th A year later he was brought back in order to have an abscess opened which had developed in the track of the cicatrix; *he left the hospital all right ten days later.*

In connexion with hepatic cysts encroaching on the pulmonary area and simulating affection of the latter possibly it may not be out of place if I give the notes of the following case.

CASE 4 —A boy, aged eight years, the brother of the last patient, was taken to England in order to have an operation performed for hydatid tumour of the right lung. On arrival the boy was placed under the care of a hospital surgeon who confirmed the diagnosis and, without resection of the rib, made an opening in the fourth intercostal space and inserted a trocar and drew off a large quantity of clear fluid; a drainage-tube was inserted into something, little or no discharge followed, the tube was soon omitted, and the wound rapidly closed The surgeon informed the mother that it was safe to take the child back to South America as the cyst would be sure to be absorbed. After a week on board ship the patient again complained of respiratory discomfort and by the end of the voyage (24 days) it was observed that he was losing flesh and had some nocturnal fever with sweating and an occasional sense of chill. He was taken immediately to the camp in the hope that the *invigorating* air of the *pampas would soon establish convalescence.* Reference, however, had soon to be made to my friend Dr. Peard who found things in a worse condition than when the patient had left for England, there being marked emaciation, sweating, and occasional rigors. The temperature was 104° F and the right chest, from the third rib downwards, was immobile, dull, and breathless Dr. Peard immediately took him to Buenos Ayres and assisted me on the day following his entry to hospital in the operation Having removed a portion of the fifth rib in the anterior axillary line healthy lung tissue presented. A needle was inserted into the lung but nothing was found. On attempting to feel for the diaphragm the lung was discovered to be densely adherent to the diaphragmatic pleura and on separating some of the adhesions the diaphragm was found bulging considerably upwards. A needle was inserted into the liver and a syringeful of pus was withdrawn Having attached the parietal to the diaphragmatic pleura by a circular suture of catgut the diaphragm was incised and a white-walled cyst presented which was opened and fully a quart of greenish-yellow pus with a large necrosing endocyst was removed from the liver. A large drain was inserted and a rapid cure followed.

I think this case tends to prove the futility of merely incising the chest wall as a means whereby hydatid cysts may be effectively dealt with.

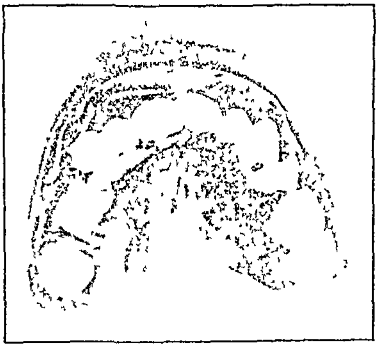
Buenos Ayres.

A CASE OF GENERAL INFECTION BY A NEMATODE, ACCOMPANIED BY HYPERTROPHIC GINGIVITIS.

BY J. DENCER WHITTLES, B.D.S. BIRM., L.D.S. R.C.S. ENG.,
CURATOR OF DENTAL HISTOLOGY AND PATHO-HISTOLOGY, UNIVERSITY OF BIRMINGHAM.

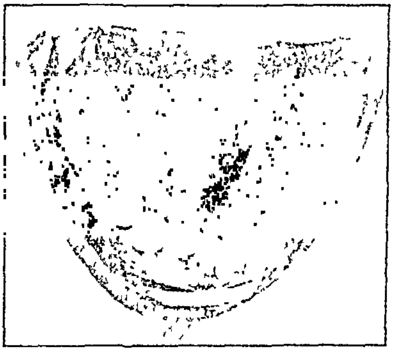
A YOUNG woman, aged 19 years, of robust appearance and weighing 9 stones 8 pounds, was sent to me at the General Hospital, Birmingham, in March, 1902, after having been treated at the Dental Hospital for thickening of the gums, which was causing considerable protrusion of the upper lip and consequent *deformity of the facial* contour. The treatment followed, according to the patient's account, consisted in cutting away portions of the gum and the extraction of loose teeth, but in spite of the free paring the growth became more marked. The illustrations (Figs 1 and 2) are from photographs of models of the upper and lower jaw respectively, made from impressions. It will be noticed that the hypertrophy is much less evident in the lower jaw, and this fact, together with the increased amount in the upper being on the right side, suggested that something had been applied with the right hand in some way. The increase of thickening came about gradually, commencing in May, 1901, so that about ten months had passed before the case came under my notice. On questioning the patient I learnt that she was very fond of dumb animals, especially dogs, and on further inquiry was informed that she was in the habit of fondling and kissing the dog at home, which had died the previous Christmas, a little more than two months prior to my seeing the patient On examining the mouth I found the greatest hypertrophy of the muco-periosteal tissue was situated between the first upper right premolar and the central incisor of the same side. It shelved off gradually to the left upper canine tooth, whilst in the mandibular alveolar border there was some hypertrophy occupying a corresponding position to the upper jaw, but to a much less degree The upper teeth were slightly moveable on pressure, and although there was so much thickening the resilience was so marked in the soft tissue as to lead me to suspect the removal of some of the alveolar process. This surmise was found to be correct as subsequent examination showed considerable absorption of the osseous tissue I extracted the right upper second premolar, which had become

FIG. 1.



Anterior aspect of the model of the upper jaw.

FIG. 2.



Model of the lower jaw.

hopelessly loose, and at the same time was thus better able to excise a little muco-periosteum for microscopical examination as I suspected from the history obtained some form of parasitic invasion. Sections after due preparation were cut and stained in various ways for demonstrating bacteria, but none were to be found after most careful examination. Instead there were to be seen in almost every section nematodes complete or portions of them (Fig. 3). This shows a field including the Malpighian layer with deeper cells of the epidermis and the submucous tissue of the muco-periosteum (gum); in the centre of the field is seen an embryo nematode. In Fig. 4 the parasite appears in a more advanced state; the curves are suggestive of its great locomotive power enabling it to reach distant parts of its host. In Fig. 5, stained by Gram's aniline gentian violet, the nematode is seen deeper in the submucous tissue than in the two former sections, whilst its length is greater and its alimentary canal is more easily discernible.

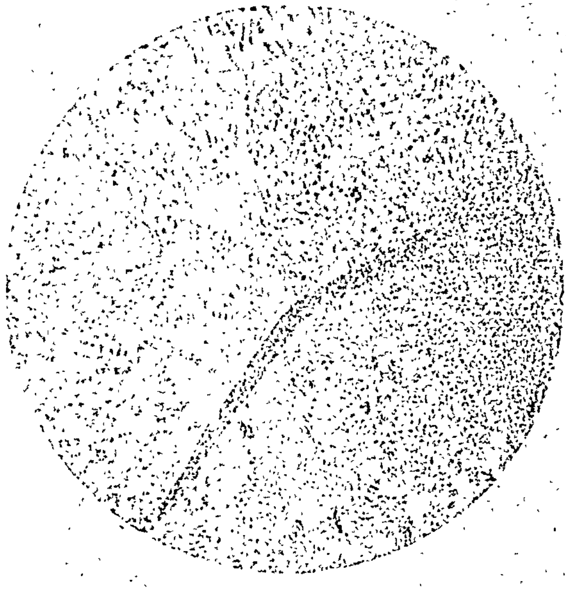
On March 22nd, 1902, the third visit of the patient, I asked Dr. E. S. Nutting to make a blood examination, which he kindly undertook, and he reported that there was a slight increase of leucocytes—this is, 8000 per cubic millimetre. There were no marked increase in eosinophile cells and no myelocytes. Dr. Nutting further stated that under a $\frac{1}{12}$th of an inch oil immersion lens the films showed the presence of one or two leucocytes in a field and never more; this statement should be borne in mind and compared with the condition found later. Having discovered the source and something of the nature of the infection my next step was to search for other signs and symptoms which might be occasioned by the parasite. The patient stated that she had had "an abscess" over the sternum in the middle line and at the nipple level about Christmas, 1901 (when the dog died), and since then at various times in other positions, but chiefly limited to the right side of the head, neck, and trunk. Down to the present time such lesions had not appeared upon either the upper or the lower extremities. In May, 1902, a "carbuncle-like" swelling was incised over the pomum Adami, from which a considerable amount of pus was evacuated; rapid healing took place. A little later another formed over the right superior angle of the scapula and close upon this another formed over the outer angle of the right eye at the edge of the hairy scalp. These "carbuncle-like" swellings were allowed to break down naturally as the patient had gone into the country for a change. The last to form was noticed on Dec. 1st, 1902. There was only a slight swelling on rising from bed in the morning and at night it was too painful to wear clothing over it, so rapid had been its formation. Many pustular swellings had occurred from time to time but these did not appear to have given the patient much inconvenience, as the inflammation was apparently only trifling, although a circumscribed button-like induration accompanied each. On Dec. 11th such a pustule formed on the inside of the right cheek. A photograph of the patient's back was taken on the 14th and it showed the scars resulting from the carbuncle-like swellings, the lowest being situated in the middle line of the lumbar region. I incised an upper darker coloured swelling seen at the base of the neck, which photographed as a black spot, but it was of reddish hue. From it there escaped some 30 minims of blood mixed with only the slightest tinge of pus, obtained by deep pressure. On microscopical examination I found at least ten of the nematodes in more or less complete forms.

FIG. 5.



Stained by Gram's method. Zeiss A A objective. No. 18 compensating eye-piece. 33 cm. camera extension.

I wish to express my gratitude to Mr. W. E. Collinge, B.Sc., F.Z.S., lecturer on zoology at the University of Birmingham, for examining the sections with me, and also to Professor W. C. McIntosh, St. Andrews University, who has kindly interested himself by writing to me at length on this subject after examining sections and photomicrographs which I had prepared. He agrees with me that the nematode was probably the cause of all the trouble and further states that the suggestion that its source was a dog was borne out by the history of filaria. The aforesaid dog was a crossbreed—a Pomeranian crossed with a Skye terrier; its previous owner had never been out of England; he had had it from a puppy up to two years old when it was given to the patient's parents with whom it had lived four years. The patient had never been away from home prior to the infection, except a day excursion to Matlock, and had never bathed in the open, so that there is little evidence of any other source of infection than the dog.

As the nematode is a transparent object it can readily be overlooked in sections unless stained with methylene blue. On Jan. 15th, 1903, Dr. James Miller, assistant lecturer in bacteriology at the University of Birmingham, kindly made a careful examination of the patient's blood and furnished me with the following particulars:—

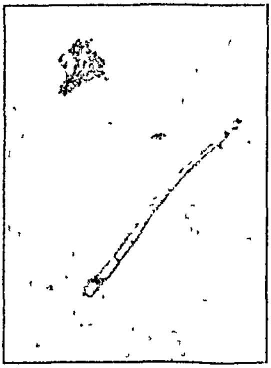
Red blood corpuscles ...	4,500,000 per cubic millimetre.
White blood corpuscles ...	9300 „ „ „
Hæmoglobin	80 per cent.

Differential Count.

Polymorphonuclears	65·3 per cent.
Lymphocytes	22·0 „
Large mononuclears	6·7 „
Transitional forms	4·5 „
Eosinophiles	1·5 „

The above averages were the result of two separate examinations. On comparing the above result with that found by Dr. Nutting there is at the present time a considerable increase of leucocytes, that is, 1300 extra per cubic millimetre will be observed. Fig. 6 is a portion of a photomicrograph of a thick untreated film of fresh blood taken from the same source as the foregoing. There is one nematode in the field exhibiting the same characters as seen in Fig. 3, photographed *in situ* in the muco-periosteum.

FIG. 6.



Thick film of fresh blood taken on Jan. 10th, 1903, untreated. Zeiss A A objective. No. 18 compensating eye piece. 33 cm. camera extension.

With regard to past literature on this particular parasite, so far as I can gather from books and papers written in English, the only similar case is described by Surgeon O'Neil, R.N., in 1875[1] who states that actively moving filariæ were found by him in papules which occurred singly, the worms measuring 0·01 inch by 0·002 inch, and bearing two black marks at the head end. According to Surgeon O'Neil the infection is said to appear after an incubation period of three days. If this is the same parasite I am able to confirm Surgeon O'Neil's statement that it is contagious, as I have found a similar parasite in the blood of the mother of the patient. A disease resembling Surgeon O'Neil's craw-craw was described some time ago[2] by Professor Neielly under the title "dermatose parasitaire." A French lad who had never been abroad became affected with a papulo-vesicular eruption resembling scabies, in which Professor Neielly found a filariform parasite somewhat like that discovered by Surgeon O'Neil in craw-craw. It had the same peculiar cephalic markings; in addition it had a well-defined alimentary canal and rudimentary organs of generation. Manson[3] suggests that "as the skin parasite in O'Neil's disease may have been an advanced form of filaria perstans this parasite normally and in pursuance of its evolution escapes from the human body through the skin after undergoing there a certain measure of developmental advance." This, I have every reason to believe, has been borne out by the skin lesions occurring in this case. So far as I can learn this case is unique and is of itself a sufficient warning that all should abstain from kissing members of the carnivora—a habit which, both with dogs and cats, is, alas, too frequently indulged in by the tender sex.

Birmingham.

A CASE OF

FULL-TIME EXTRA-UTERINE PREGNANCY; FŒTUS LODGED IN A CAPSULE OF THE OVARY IN A PERITONEAL SAC RESEMBLING THAT OF THE TUNICA VAGINALIS.

BY JAMES OLIVER, M.D., F.R.S. EDIN., F.L.S.,
PHYSICIAN TO THE HOSPITAL FOR WOMEN, SOHO-SQUARE.

A WOMAN, aged 33 years, who had been married nine years, came under my care at the Hospital for Women on Dec. 31st, 1902. She had had three children and one miscarriage. The last child was born three and a half years previously and since the birth of this child she had enjoyed good health. On Jan. 12th, 1902, the patient menstruated as usual and thereafter no hæmorrhagic discharge from the vagina was noted until Dec. 13th—i.e., during a period of 11 months there was complete amenorrhœa. The hæmorrhagic dischage which appeared on Dec. 13th continued without cessation until I removed the fœtus and placenta by laparotomy on Jan. 1st, 1903. Although this hæmorrhagic discharge flowed continuously for 18 days it was never large in amount and it ceased immediately after the operation. When the menstrual discharge failed to make its appearance in February the patient considered herself pregnant and as the gestation ran its full course without producing one symptom different from those which she had experienced during her previous pregnancies she did not seek any opinion regarding her condition until she observed that in spite of the reappearance of menstruation the abdomen did not diminish in size. The patient felt the movements of the fœtus for the first time about the end of June, but she thought that she never felt them after about the middle of October. Pain was never complained of and no labour-like pains were ever experienced. The physical signs were as follows. The abdomen, I found, was occupied centrally by a large globular swelling extending from the pelvis to four and a half inches above the umbilicus. Palpation detected the various parts of the fœtus, but these were not more easily defined than we find them in many cases of uterine gestation. No sounds were detected [illegible] ...ur. The breasts displayed the [illegible] of pregnancy and from both [illegible] ...ained. The cervix uteri, which was not specially soft, was but little deviated from its normal position in the pelvis. The body of the uterus could not be defined and separated from the abdomino-pelvic swelling, but the cervix did not appear to be structurally continuous with the latter.

Operation was performed o[illegible] was opened mesially betwee[illegible] account of the then revealed [illegible] to the tumour and as there was promise that I might remove intact the sac containing the fœtus and placenta I extended the incision to four inches above the umbilicus. The right mesovarium and mesosalpinx were spread out over the lower right half of the tumour and in consequence of this state of affairs the posterior wall of the uterus was closely applied to the left anterior surface of the tumour. The uterus was slightly enlarged. The tumour elsewhere was enveloped by, and adherent to, omentum and bowel. The right mesovarian and mesosalpinx were ligatured and severed from the tumour and the uterus thereafter sank down into the pelvis. The omental and bowel adhesions were then dealt with and after freeing these the tumour was found to have a broad and thick attachment to the posterior abdominal parietes. The sac containing the fœtus and the placenta was drawn out of the abdominal cavity and pressed over towards the left flank. It was freely incised and the fœtus and placenta were now extracted therefrom. The wall of the sac varied in thickness from a quarter to three-quarters of an inch except over a small area about 2½ inches in diameter at its upper and right border where it was extremely thin. It was thickest towards its junction with the posterior abdominal parietes with which it appeared to be structurally continuous. On this account and because the placenta had been implanted over this situation I excised the anterior half of the sac and stitched the remaining portion to the anterior abdominal wall, leaving an opening of sufficient size to allow of free drainage. Eventually the inner lining of the sac was shed piecemeal and on Feb. 3rd granulation from the bottom had so progressed that the cavity was almost obliterated and convalescence was well advanced.

[3] Patrick Manson, M.D., LL.D.: Tropical Diseases, 1903.

The above is the fifth case of full-time extra-uterine pregnancy which I have had to deal with and all have been operated upon successfully. In two out of my five cases the fœtus arrived at maturity without one symptom different from those of a normal uterine pregnancy being experienced. In three there had been occasionally a hæmorrhagic discharge from the vagina during the life of the fœtus. In these three pain more or less severe had been complained of from time to time during the evolution of the pregnancy but in none of the five cases were labour-like pains experienced, not even at or about the time when the fœtus probably died. In two only was there extrusion of decidual membrane per vaginam. In one case only was there elevation of temperature and in this suppuration of the sac had occurred and the fœtus floated in about six pints of creamy inodorous pus. In three the fœtus and placenta were lodged in the substance of the broad ligaments: two were on the right side and one was on the left. In one only of these broad ligament cases was I able to extract the fœtus from its nidus without opening the peritoneum; in the other two the reflection of this serous membrane from the broad ligament on to the anterior abdominal wall had not been sufficiently elevated to allow of this, consequently the upper portion of my incision opened the peritoneal cavity in both more or less extensively. In two of my five cases the peritoneum was incised co-extensively with the abdominal wall generally and the tumour containing the fœtus and placenta was to all intents and purposes in both covered in its entirety with peritoneum of its own. One of these, which was published in THE LANCET of July 25th, 1896, p. 241, was undoubtedly an example of ovarian gestation; the other is the case which I now record and in this the fœtus and placenta were lodged in a peritoneal sac—a sac similar to the so-called ovarian capsule found in some vertebrata. This sac, except at its right upper border where it was thin and appeared to be composed of adventitious membrane, was dense and thick. Originally it communicated more or less freely with the general peritoneal cavity but at an early stage of the gestation it became closed by new membrane and in this way the very thin portion just referred to may be accounted for. At first it was difficult to explain the attachment of the sac to the posterior abdominal parietes, but this became comprehensible when one recalled that in some cases the ovarian capsule is formed in a peculiar manner by division of the ovarian ligament and that in such the ovarian ligament may be traced in the posterior abdominal parietes up to the level of the lower border of the kidney. The ovarian capsule is a structure quite distinct from the ampulla of the tube and in some cases the tube traverses for a distance the parietes of this capsule. In operating upon cases of intraperitoneal hæmatomata resulting from ectopic gestation one occasionally finds the ovary more or less concealed in a peritoneal sacculus and I am inclined to think that this is an abnormality of not infrequent occurrence. In cases of full-time extra-uterine pregnancy and quite independently of any operative interference the menstrual function tends to reassert itself in from four to 12 weeks after the death of the fœtus—i.e., at about the same time as after normal delivery when the child is either born dead or is not suckled. It is noteworthy, however, that although the menstrual discharge is not, as a rule, more profuse it is apt to be more prolonged in the former group of cases.

Gordon square, W.C

NOTE ON THE ETIOLOGY OF THE SLEEPING SICKNESS.[1]

BY ANNIBAL BETTENCOURT,
AYRES KOPKE,
JOSÉ GOMES DE REZENDE, JUN.
AND
ANNIBAL CORREIA MENDES,
MEMBERS OF THE PORTUGUESE COMMISSION.

THE bacteriological researches which we have undertaken in order to illustrate the etiology of sleeping sickness were systematically carried out principally on those organs and tissues of the body in which, guided by the knowledge of former pathological investigations and by the results obtained in the first necropsies which we made, we knew that the principal lesions of the African disease, which is anatomically a meningo-encephalo-myelitis, are found.

In our first report, dated June 9th, 1901, regarding the six cases observed in Principe, we said that the preliminary and restricted work which up to then had been accomplished seemed to "guide us in the sense of the infectious nature of the sleeping sickness." Two months afterwards (August 10th), in Loanda, we first proved the existence of a diplo-streptococcus in the cerebro-spinal fluid *intra vitam* (six positive results in nine cases) and in the subarachnoid exudate (13 times in several necropsies which were performed); the principal characters of the germ could only be demonstrated in an imperfect and summary way owing to the absolute impossibility of making a complete study of it up to that date. These results were published in September, 1901.[2] In Lisbon (August 7th, 1902) we finally gave a demonstration, illustrated by diagrams and by the exhibition of specimens, of cultures, and microscopical preparations which had been collected in the course of a great number of researches from the cerebro-spinal fluid obtained by lumbar puncture *intra vitam*, and from the exudate and fluid of the *ventricles obtained after death, from* the blood, ganglions, and spleen, demonstrating also in numerous microscopical sections, especially of nervous tissue, the existence of the parasite previously described lying within and outside the vessels. We therefore particularly pointed out, in order to admit of no doubt, that the micro-organism in question ought to be included in the streptococcus group and we proposed to give to it the name of "hypnococcus."[3] The following were our words: "The general description of the principal characteristics of the hypnococcus being given, let us see if it is possible to determine its place in bacteriological classification. We rather considered it, in our first report, as a type of transition between the streptococcus and Fraenkel's diplococcus. We can, however, affirm to-day that it is easy to distinguish it from the latter. It is enough to say in order to separate it from Fraenkel's diplococcus that it grows on gelatin and in other media at a temperature lower than 24° C. But we wanted to go further and we followed the plan proposed by His to establish the differential diagnosis between the pneumococcus and the bacteria of the streptococcus group. Water is mixed in equal portions with the serum of oxen, properly alkalinised and sterilised, and we add 1 per cent. of inuline. This sugar is fermented by the pneumococcus and a change takes place in reaction, from alkaline it becomes acid and causes the coagulation of the medium. Our diplococcus grows well in His's fluid and the reaction is not modified nor does the fluid coagulate even after a month's stay in the incubating oven."

---

Ministro da Marinha, composta de Annibal Bettencourt, chefe da Missão, Ayres Kopke, José Gomes de Rezende, jun., e Annibal Correia Mendes. (Revista Portugueza de Medicina e Cirurgia, Nos. 139 a 144, Agosto a Outubro, 1902.)

We read lately in a medical journal[4] a previous report of the bacteriologist Castellani, a member of the English Commission sent to Uganda to study the sleeping sickness, in which he found while making his investigations in the same manner as we had already done a streptococcus in the cerebro-spinal fluid of patients during life and after death, which the author thinks is a different one from ours. This idea probably must be due to the fact that Castellani only knew of our first reports, which were erroneously translated,[5] in which the description of our bacteria might give place to some doubts in regard to its bacteriological classification.[6] However, after this work we described it more precisely and considered it as belonging to the numerous streptococcic group (August 7th, 1902).

It is necessary to say that, though some divergencies exist between what we said in our first report regarding the bacteria and the one which Castellani found in Uganda, they are not important, and we think do not justify Castellani in establishing such a radical distinction. It might be considered that the difference either proceeds from the diversity of the two bacteria or from the conditions under which the observers worked. Castellani considers only the first proposition and he completely forgets the second, which was in reality the principal one. The proof of the small value of the facts put forward by Castellani to establish this difference is shown by himself in the way in which he concludes his report, being apparently exactly of the same opinion as we were in August, 1901. We then said: "As to the bacteriological classification of the diplo-streptococcus only further experience and time can decide. Its analogies with Fraenkel's diplococcus on the one side and with the streptococcus on the other are certain; but the *organism cannot be with certainty relegated to either group*, though there is close relation between the two, as all bacteriologists allow. What we have said until now of our diplococcus is that it seems to be a transition between Fraenkel's diplococcus and the streptococcus." Castellani says the following about the bacteria which he found: "From the description just given I think that this germ must be considered a new variety of streptococcus. Every bacteriologist knows how difficult it is to differentiate sharply the varieties of streptococci on account of the numerous transition forms that occur, even a sharp separation between the streptococcus pyogenes and the streptococcus lanoceolatus (Fraenkel's diplococcus) seeming to many authors to be impossible." Lower down he says: "I think that this organism is a distinct variety of streptococcus, to be classed between the streptococcus pyogenes and the streptococcus lanceolatus (Fraenkel's diplococcus), and it might be called the streptococcus of the sleeping sickness." This means that Castellani and ourselves in our first reports both came precisely to the same conclusion and expressed ourselves in identical terms. We cannot understand how this could happen if in reality distinct species were in question, the studies being made quite independently one from the other. The same impression on the investigators having been left, although there was a considerable difference of time and place at which the investigations were made, can only signify that the result of the researches was the same, or, in other words, that the two micro-organisms isolated by us in the West of Africa and by Castellani in the East are the same.

Let us see, however, upon what basis Castellani considers his bacillus to be a different one from ours. We are sorry that he did not see the Portuguese journal in which we published our second work, which was of much earlier date than his, for on reading this all doubts should cease and everybody would think it superfluous to speak of a question of priority. Castellani says, as regards the diplo-streptococcus of the Portuguese, he does not think that any confusion can arise. "The Portuguese state that the culture of their germ generally failed every time on the usual media like agar, gelatin-agar,[7] &c., and with gelatin they never succeeded in obtaining cultures." The only differences, then, are merely that our cultures nearly always failed in the usual media and that we did not obtain them on gelatin. We said, conformably to the text of our report, "The diplo-streptococcus found by us grows badly in nearly all the nutritive media usually employed. The bouillon, agar-agar, simple or glycerinised, nearly always fail. The liquid proposed by Martin for the cultivation of Löffler's bacillus and obtained by the maceration of the pig's stomach gives a much better result, especially if we can make it solid by the addition of agar." What is concluded in our text is that the bacteria grows badly, but this does not mean that it does not grow at all. We add that it grows much better in Martin's media, for one c[illegible] sents some of the colonies grow[illegible] this author. These facts ough[illegible] pose that the absence of constant growths in the media referred to proceed more from their defects than from the biological peculiarities of the bacteria. In fact, in our first report we showed that the failure to obtain a growth was really owing to the short time occupied by our researches and to the methods we employed *for isolating the organism.*

We may say that for the preparation of our media we always employed Witte's peptone, which being very rich in albumoses is not so favourable for the germination of the bacteria as some others are. Nicolle and Remlinger especially point out this fact in their excellent book, "Traité de Technique Microbiologique" lately published; we verified this recently on different bacterial species including the hypnococcus. This last fact is no less important and may have greatly influenced our results, especially in the inoculations performed with the products procured from the human body because in these circumstances, as it is known, the bacteria are more easily influenced by the unfavourable conditions of the media. In Martin's media, which have for bases a peptone prepared *ad hoc* in the laboratory, the same thing does not happen and that explains the better *development.* *Finally,* Wassermann isolated in acute articular rheumatism a micro-organism belonging to the streptococcus group which only grows in strongly alkaline media, to which has been added Chapoteau's peptone, cultures not being obtained when Witte's peptone is used, as usually employed in Germany. All this is set aside because for a long time we have managed to obtain, as Castellani did, development in all these media. Months before the publication of his work we published a description of our cultures on agar, bouillon, and potato, in which we obtained identically the same results as Castellani. We also point out the absence of the coagulation of milk and the absence [illegible] in respect [illegible] with us. [illegible] on gelatin, for the simple reason that we have already obtained cultures in this medium in Lisbon—flesh pepton-gelatin and Martin gelatin. These cultures were exhibited at the time of our conference (August 7th, 1902) and the description of them may be found in the *Revista, Portugueza de Medicina e Cirurgia Praticas*, where we state the reasons to which we attribute the negative result obtained in Loanda.

We never made direct inoculations of morbid products in this medium, so we cannot say if they would be successful, nor does Castellani say in describing the streptococcus if he made use of all the media which he speaks of for the primary cultures or if some of them were only employed in the subculture; this makes a great difference with regard to the resu[illegible] which [illegible] tidis of [illegible] all the [illegible] germs d[illegible] them dc[illegible] remarkable is our agreement in various points of the description. Some have already been mentioned. We have also shown various instances of form and size, and the existence of groups from the [illegible] may be shorter or lo[illegible] human subject or fr[illegible] refers. The charac[illegible] aspect which the hypnococcus takes according to this author's description, all is in complete agreement with ours.

We further point out, before concluding, that our investigations were not limited to culture and microscopical examinations of the pathological fluids of the organism. We also studied numerous microscopical sections, especially those of the nervous tissue, and were the first to find and mark out the presence of *the hypnococcus.* Such sections were also

---

[illegible]

[illegible] sent [illegible] ow- [illegible] seen by Patrick Manson some time ago in London, by Marmorek of the Institut Pasteur in Paris, and were finally presented by Mense at the last Colonial Congress assembled in Berlin.[8] How can it be suggested that the bacteria so often isolated by us in pure culture may not be the same as the one seen in the sections and exudates, the identical morphology being given? and how can the germ isolated by Castellani from the same regions of the body where we obtained it during life and post mortem, not be the same we saw in our microscopical sections?

After all this there is not the slightest doubt that Castellani's bacterium is the one which we described and that his investigations are a complete confirmation of ours. This is the original and important fact. The priority in the question is relatively a secondary one, as no one can honestly and *sine irâ* contest that it does not belong to us; but the works of this member of the English Commission, done quite independently of ours and in quite different and distant regions, do not in the least lose their merit or the important signification they bear for the clearing up of the etiology of sleeping sickness. It is, in fact, the first time that etiological researches of the African lethargy have been thoroughly verified and identical results arrived at.[9]

ON A CASE OF ARTERIAL OCCLUSION AND GANGRENE.

BY ANDREW DUNLOP, M.D. EDIN.,
CONSULTING PHYSICIAN TO THE JERSEY GENERAL DISPENSARY AND FEMALE ORPHANS' HOME.

IN November, 1899, I was consulted by a retired officer of the army on account of pain in the left leg and foot. He was a spare, active man, in his fifty-third year, with a complexion ruddy from enlarged capillaries and with the skin of the hands also of a high colour. In India, when a young man, he suffered from malarial fever and dysentery and he also had dysentery while in Egypt in 1882. Of late years he had been liable to dyspepsia, and in 1898 he had tobacco amblyopia which afterwards improved. Some time in the summer of 1899, I think, I had attended him for painful redness and swelling affecting the ball of the left great toe and running up the dorsum of the foot between the first and second metatarsal bones. The pain which he complained of when I saw him in November was intermittent, occurring in paroxysms which often came on in the early hours of the morning. It ran down the front of the leg and along the dorsum of the foot and was felt in the ball of the big toe and the distal part of the foot. The foot was sometimes dark red and congested, when it felt hot, and sometimes it was pale and cold, conditions resembling the syncopal and asphyxial states of Raynaud's disease. Stiffness and some pain behind the knee-joint were also complained of. The heart, though perhaps a little weak, was perfectly normal and there were no indications of atheroma or arterio-sclerosis in any of the accessible arteries. The urine was free from albumin and sugar and in all respects normal. The lungs were healthy. The tongue was somewhat furred and there were some dyspeptic symptoms but the abdominal organs were otherwise healthy. The temperature was normal. Later, pulsation was observed to have ceased in the posterior tibial artery and the dorsal artery of the foot; the pains became more frequent and severe and the varying conditions of heat with dusky redness and coldness with pallor became more marked. Pains of a slighter degree were also felt in the right leg and down the arms, and the right foot also showed some signs of varying congestion and pallor, as also did the hands.

In the spring of 1900 he improved somewhat for a time, but about May he got worse again and a black spot formed on the under part of the distal phalanx of the great toe and another on the tip of the little toe. The extreme tip of the little toe gangrened and the process there made no further advance but it slowly went on in the big toe till it was entirely black and mummified. A distinct line of demarcation, well beyond the joint, formed in, I think, the month of July, but it made one or two advances during the next month or two. In September there was a good deal of constitutional disturbance due, apparently, to septic absorption, the temperature rose, and he had a severe attack of aphthous stomatitis. At the beginning of October, as the line of demarcation was making no further advance, Mr. A. E. Hind removed the gangrened toe by cutting through the first phalanx where the separation had taken place down to the bone, just beyond the metatarso-phalangeal joint. After the operation the patient improved rapidly and in a month or two the wound had healed and he was able to move about again.

From the end of 1900 to the spring of 1902 the patient was in excellent health, though he had occasional pains in the legs. About the month of April he consulted me on account of occasional attacks of sudden and severe pain at the bottom of the sternum and over the præcordial region, seizures which had very much an anginal character. A little later he had pain running down the sciatic nerve on the right side, and some time in May he began to have sharp attacks of pain running down the front of the right leg, the paroxysms very frequently occurring in the early morning as they had done in the other leg. In June the right foot was frequently, indeed mostly, hot and congested, and sometimes cold and pale, and soon no pulsation could be felt in the posterior tibial or in the dorsalis artery. About the end of the month two black spots appeared on the sole of the foot, one on the heel and the other on the under surface of the little toe, just on the bend of the first joint. In July suppuration occurred at the seat of the black spot under the toe and some matter was let out by a small incision. In August unhealthy-looking ulceration began to extend from this point, gradually spreading two or three inches up the outer side of the foot, and the toe became purple and gangrene set in. By the middle of the month the toe and the ulcerated part of the foot were completely gangrened and a line of demarcation had begun to form; but the next toe was evidently becoming implicated. All this time the patient's condition remained good. The temperature was normal or only slightly raised sometimes. The pulse was good but occasionally quick and not very strong. The urine was normal.

About the middle of September the fourth toe was gangrenous and the line of demarcation was advancing onwards and upwards. The constitution was now showing the effects of the disease. The temperature was frequently raised, though not often above 100° F., and at the end of the month there was a rather sharp attack of aphthous inflammation of the mouth and throat, as during his last illness. There was also an aphthous ulcer on the conjunctiva of the left eye which gave rise to inflammation. During all this time the pain in the leg and foot was frequent, almost constant, and often very severe.

On Oct. 4th, as the line of demarcation seemed at last to be stationary, the gangrened parts were removed by Mr. Hind, who cut through the fourth metatarsal bone and disarticulated the fifth at its tarsal articulation. The raw surface left looked pale and bloodless. About three weeks later the second and third toes had become gangrenous and a line of demarcation had formed on the dorsum of the foot which included them, though it was not developed on the under surface. The great toe had also a dry gangrenous patch on the tip and the nail had been removed owing to suppuration in the matrix. It was then decided that the dead and dying parts should be removed, and Mr. Hind, assisted by Dr. J. R. Muir, R.N., separated them by disarticulating the remaining four metatarsal bones at their tarsal articulation and making a flap of the sound skin of the sole to cover the wound made at this operation and the still incompletely healed one left by the last.

For a day or two after the operation the temperature rose in the evening to 102° and there was some general constitutional disturbance, but great improvement of the general condition soon set in. The mouth, which was still sore, got better, the inflammation in the eye gradually subsided, and an ulcer on the back part of the heel which had given some trouble began to mend. A week or ten days after the operation a part of the flap which was stretched over the internal cuneiform bone sloughed and the bone protruded through the opening. The projecting part became necrosed and on Dec. 1st it was found to be loose and was easily removed, leaving a vigorously granulating surface behind it. After the operation the attacks of pain still continued but they became less frequent and severe. There was also occasional pain in the left leg and foot and for a time the sole of the foot was sometimes congested and occasionally the foot was pallid. Pain was also complained of in the left arm and the fingers of both hands became bloodless now and then. By the end of January the wound had completely healed, though there was still some discharge coming from under the flap, and the patient was looking well and beginning to get about.

---

[8] Archiv fur Schiffs- und Tropen-Hygiene, Band vii., 1.

[9] It is convenient to correct here a mistake in the English translation of our first report. It was said that we isolated constantly the diplococcus from the blood. This is absolutely incorrect. What we clearly confirmed was that in four cases examined in this point of view we only found it once. To-day we can add that we have had two positive results in seven cases. Castellani only isolated it once. We have here another point in which Castellani's researches agree with ours.

At about the middle of February, however, an apparent obstruction of the right femoral vein occurred. There was pain in the groin, the stump of the foot became swollen and purple, and there were paroxysms of severe pain in it. The whole leg was œdematous and the protruding bone in the stump became inflamed and bare. A fortnight later a similar attack took place on the left side and it was over a month before both legs had recovered and even then there were frequent pain and great tenderness in the stump of the right foot. The patient's health meanwhile improved greatly and by the middle of April the disease seemed to have entered upon another period of quiescence, though the foot still continued to give pain.

Though a description of the condition of the affected arteries cannot be given—fortunately for the patient—and though perhaps the possibility of slow-forming thrombus in atheromatous or sclerosed vessels cannot be quite excluded, this case has all the appearance of one of Friedländer's arteritis obliterans.

The heart was normal, the urine was free from albumin and sugar, and there was no evidence of atheroma or sclerosis in any of the accessible arteries. The obstruction could not have been caused by embolism, the lapse of time between the commencement of the symptoms and the occurrence of gangrene was too great. The arterial occlusion was evidently a gradual one. In this connexion the varying congestion and pallor of the feet are interesting, as they recall the symptoms in Raynaud's disease. This was most marked in the first attack; in the second attack the right foot was mostly congested and hot. The pains, from their severity and mode of occurrence, often led me to suspect neuritis, though there was perhaps not more wasting of the leg muscles than could be accounted for by disuse of the limbs and I did not notice any abnormalities of cutaneous sensation. The anginal attacks are also of interest when it is remembered that in specific cerebral arteritis—a typical obliterative arteritis—such attacks have been noticed and found to be due to affection of the coronary arteries. In this case, however, the attacks lasted for only a short time and did not recur, so they were probably of a purely neuralgic character. There were also pains in the arms, mostly the left arm, and the fingers were often dead and pale and the hands congested.

Friedländer[1] in his paper gives no clinical account of the disease; he confines himself to a description of its pathology and morbid anatomy. The morbid process begins by inflammatory cell growth in the inner coat which is thickened at the expense of the lumen of the artery. The other coats become affected and subsequently connective tissue formation sets in and the vessel is transformed into a fibrous cord. Complete obstruction is sometimes delayed by the continuance of the first, non-fibrous, stage in which the artery may not be completely blocked by the yet soft granular tissue, or occlusion may be hastened by the formation of thrombi in the partially obstructed vessel. The veins may also be affected. Friedländer says that obliterative arteritis is not so often primary as secondary to disease of the surrounding tissues.

Von Winiwarter[2] relates a case closely resembling that of my patient. The affected foot was amputated about four inches above the malleoli and he gives a most careful and detailed account of his examination of the parts that had been removed, pointing out that the morbid changes in the vessels were those previously described by Friedländer as arteritis obliterans. The veins were affected as well as the arteries and he also found that the posterior tibial nerve and its branches were involved and nearly doubled in thickness.

Dr. Prioleau in his Thèse (Paris, 1887) on "Rétrécissement Généralisé des Artères" does not seem to differentiate obliterative arteritis from arterio-sclerosis, but amongst his cases are some which resemble that of my patient and he describes morbid appearances similar to those recorded by Friedländer and von Winiwarter.

Dr. F. W. Mott has an excellent article on obliterative arteritis in vol. vi. of "Allbutt's System of Medicine," and both Dr. Prioleau and Dr. Mott give a full list of references, only one or two of which, however, I have had the opportunity of consulting.

St. Heliers, Jersey.

A FURTHER NOTE ON THE THERAPEUTICS OF A 10. PER CENT. SOLUTION OF SODIUM CINNAMATE IN GLYCERINE INJECTED SUBCUTANEOUSLY.

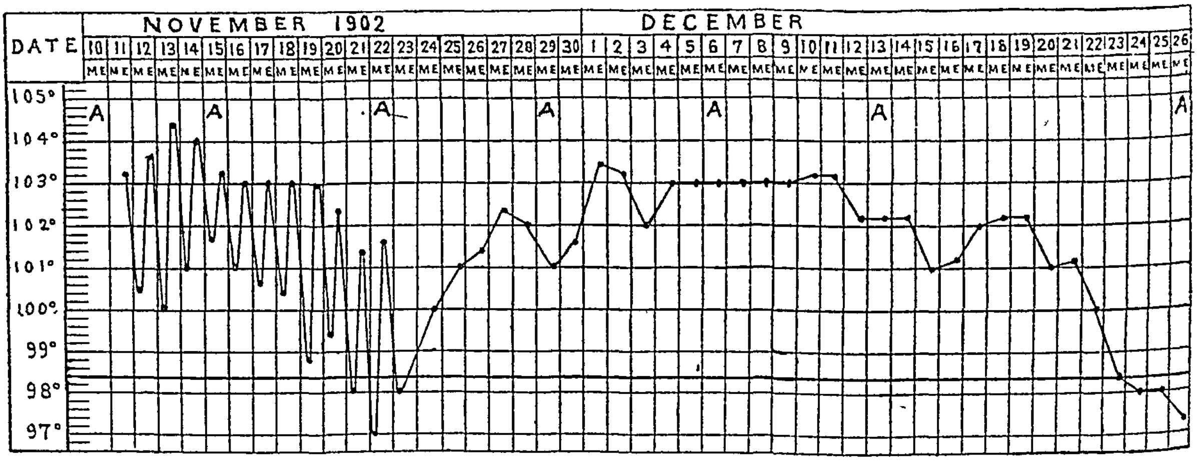
BY LOVELL DRAGE, M.D. OXON.

IN the preliminary note published in THE LANCET of July 12th, 1902, p. 66, the groundwork of the treatment was briefly mentioned. Surprise has been expressed that a drug could profoundly alter the conditions of two diseases which are apparently so dissimilar in every respect as cancer and tuberculosis. However, there are points connected with them which appear to lead in the direction of the thought that, whatever dissimilarity there may be in their external manifestations, the conditions which precede the alterations in the structure of the cells which are affected are alike in type and that the general conditions of health in patients diseased either in the one or in the other way are equally alike in type. The difference in the alteration in structure is in detail, profound as that difference is. The difference in the general conditions of health is equally in detail, but not so fundamentally. In both diseases there are conditions intimately connected with the cells attacked which precede the conditions of actual disease and in both the results of the disease are manifested by the condition known as cachexia, varying in details even amongst those smitten by the taint of the two diseases. It is necessary, therefore, in the case of both diseases to consider very carefully the conditions affecting the cells themselves before they are attacked by the one or the other disease. Every cell, however low in the scale of organisation, has certain properties of its own, functional as well as structural. These are properties which may be designated as inherited properties in the case of some, acquired properties in the case of others. It is impossible to state that in cells affected by these diseases there is any evidence to show that both properties do not exist, and, indeed, it may be stated quite definitely that in the absence of inherited properties those acquired are only with difficulty obtained. If this be accepted there can be little difficulty in finding the reason for the many and great differences not only in the structural alterations noted in both diseases but also in the progress and clinical history of them. Varied as [illegible] much more varied are [illegible] ...ngs. The variations which can be produced and perpetuated in many living cells are well known not only to the scientist but also to the stockbreeder and the gardener, although the latter know them in bulk, the former in sample. With the differentiation of the bacillus of tubercle and the demonstration of its connexion with the causation of the structural alterations in the cells which it attacked an important phase of knowledge was undoubtedly opened and so far as the improvement in the treatment of the disease goes there has resulted something. However, it never appeared to me that there was reality in that improvement. Under various treatments and under no treatment at all many patients become well—that is to say, that the masses of cells which had been attacked by the disease became cured in the manner adopted by nature.

The main lines upon which treatment has been generally based have been the improvement of the general condition of health by providing to the blood circulating in the vessels an abundant supply of oxygen and of nourishing food. It has been difficult in most cases, if not all, to say whether the drugs usually administered had any good effect, and still more difficult to find a satisfactory physiological reason for their administration. For many years past the speculation has ever been present with me, Why should it be possible to control the bleeding resulting from fibroid tumours of the uterus by the continued internal administration of a strong decoction of cinnamon sticks, and, indeed, to reduce their bulk? It appeared probable that something was supplied through the circulation to the tumour which influenced its growth. Subsequently, on the administration of the oil in cases of tuberculous and cancerous affections, and especially the latter, it appeared as if some modification of the progress of these affections was achieved. This being the case, I thought it right to ascertain the effect of placing a patient under treatment before removing a breast affected by scirrhous cancer. I therefore treated the patient before operation with oil of cinnamon and continued the treatment for three months afterwards. As the breast was only removed in the spring of 1901 it is impossible to speak definitely, but there is one point which struck me very forcibly and that was the rapid improvement in the health of the patient. I do not recollect any patient whose breast was removed for cancer to improve so rapidly, or to remain in such good health as this patient preserves up to the present date. Not only is this so, but in the spring of last year the patient showed me an old sebaceous cyst in her back. This had all the appearance of an atrophic cancer. She told me that she had had it for years, but did not think of mentioning it to me when I removed her breast. I was very anxious that the sodium cinnamate should be injected forthwith, but she refused any sort of treatment. She now tells me that "the place has dried up with a sort of scab."

The inference which I draw, although it is obvious that others may, and probably will, be drawn, is that both the breast and the cyst were affected by cancer at or about the same time and that the oil of cinnamon treatment profoundly modified the progress of the growth of the cancerous cyst and has so far prevented any return of the cancer of the breast. It may here be remarked that the breast was only removed by the old-fashioned method and that the axilla was not opened up.

The period has now arrived when I can take up the thread of my discourse at the date of the publication of the paper which I wrote for THE LANCET last year. Since that date I have been actively using the glycerine solution of cinnamate of sodium. The accompanying chart will demonstrate the effect of the drug upon an attack of acute pulmonary tuberculosis in a young man, aged 28 years, engaged in a printing office. I was asked to undertake his case by a patient of mine who told me the distressing and pressing nature of the case. A young man, married, with a young child and a wife dependent upon him, was told that he was a bad case and unlikely to live. He was at the time an out-patient at the Brompton Hospital and was rapidly losing flesh. His illness began in the autumn whilst he was taking a holiday. On Oct. 10th he first saw a medical man who eventually told him that his right lung was affected and that he must attend the Brompton Hospital, a course which he adopted. Physical examination revealed comparatively little, expectoration was very small, there were no moist sounds to be heard, but breathing on exhalation at the right apex was prolonged slightly and more noisy than was normal. I agreed with the other medical opinion that the case was one of early and acute pulmonary tuberculosis. The chart speaks for itself; the morning temperature was not taken after Nov. 24th. Seven injections of the 10 per cent. solution of cinnamate of sodium were given at the dates marked upon the chart. The man went to his work in the office a week after the first injection and remained at work until the end of the treatment. He gradually put on flesh, improved in spirits, and although there was a considerable amount of cough and expectoration during the progress of the case there was always a continued improvement in health, and the patient at the present time has no cough, is as fat as he should be, and is without any symptoms except those of good health.



Case of acute pulmonary tuberculosis in which cinnamate of sodium was injected. A, Injection of 30 minims. Morning temperatures were not taken after Nov. 24th.

A second case to which I should like to draw attention is that of a young girl who had been troubled for some months with chronic diarrhœa. When she first came under observation she was emaciated and passing often more than 12 motions a day. On examination nothing could be detected in the abdomen or chest abnormal in character, but her appearance was that of a tuberculous patient. Various treatments were tried but nothing produced any diminution in the flux from the bowels. The glycerine solution has been injected at varying intervals into the flanks since then. Her bodily condition has steadily improved and the number of actions of the bowels has been diminished by one half. Nothing more can be said at present about the case, but it appears probable that a satisfactory issue will be obtained.

The result of experience of the use of the drug so far has led me in the direction of the belief that in early cases of pulmonary tuberculosis a successful issue may be predicted with confidence and that in all more advanced cases amelioration may be guaranteed with equal confidence. No treatment obviously can restore cells which are destroyed absolutely and if there are not sufficient cells remaining which are capable of performing their work the organ of which these cells are a part can either not perform its functions at all or only in part. So long as healthy cells remain in an organ sufficient to carry on its work, just so long has treatment by cinnamate of sodium or any other treatment a chance of preserving the life of the owner of the organ. The case of early tuberculous laryngitis mentioned in my first communication is arrested and the patient is enjoying good health.

It is not my purpose to refer to other tuberculous cases at the present moment, but one of cancer of the tonsil, with a mass behind the angle of the jaw, presents points of interest. It is a case which has been seen by Mr. H. T. Butlin at St. Bartholomew's Hospital. The cinnamate solution has now been injected at varying intervals since the early autumn of 1902 Although the duration of the growth is not less than 12 months there is no difficulty now in swallowing, one small gland below the large mass has disappeared, and the action of the drug seems to have caused a fibrous incapsulation of the mass behind the jaw; the skin *is quite freely moveable over the mass The patient feels* little or no pain and generally appears to be in a condition unusually favourable in such a case, so far from the commencement of the disease I am now using injection of doses as large as 60 minims of a 11 per cent solution and with apparently quicker results. No symptoms of inconvenience are felt from the larger injection, but the pain caused *is of somewhat longer duration The amount of pain is not* very great and this is judged because patients readily return for treatment

Hatfield

RESEARCHES ON HIBBERTIA VOLUBILIS

BY JOHN REID, M A, M D, C M ABERD

THE parts of the plant used in the following investigation were the fruit and the pistils which had been preserved by drying They were obtained from Coraki and Manly Beach two places in New South Wales The plant was identified by the late Baron F von Muller, who has also supplied the bibliography[1]

Extraction with acetic acid and subsequent precipitation give the alkaloid dillenine, extraction of the residue with boiling alcohol takes up the oil, while by boiling the residue with liquor potassæ a solution of potassium dillenate is obtained, from which insoluble calcium or lead dillenate may be prepared and the acid eventually isolated On neutralising the potassium salt with lime an acid foam may be skimmed off, it is the colouring matter which I *propose to name "stephenic acid after the late Rev* George Stephen of Fordyce Banffshire On precipitation with ammonia the acetic acid extract yields a brown coloured neutral resin which is insoluble in ammonia water, and chloroform but dissolves in acids forming a tasteless solution Dillenine is soluble in chloroform which is used for isolating it, acicular crystals are deposited from the solution The dillenate of dillenine is deposited from the chloroform solution in transparent laminæ more or less perfect The acetic acid extract contains a little dillenic acid shown by the sherry colour produced on the addition of ammonia. In spirituous solution dillenine lessens the colouring power of tincture of guaiacum on a cut surface of potato When heated it becomes charred and burns with an odour of burning feathers An aqueous solution of the dillenate or acetate precipitates mercuro potassic iodide and iodurated iodide of potassium Given internally in doses of less than one grain of the dried substance it causes a lowering of the blood pressure, the pupil also becomes dilated and remains so for a few hours with disturbance of the power of accommodation

The oil is thick almost like palm oil and possesses the sickly odour of the flower When boiled with caustic potash it becomes whiter but is not saponified By keeping it becomes resinous in appearance It is soluble in benzene, water does not give a precipitate with perchloride of iron, gum or gelatin Stronger solutions of its salts with alkali metals show the following reactions —1 Ferrous sulphate gives a colourless flaky precipitate in a solution which is greenish by transmitted light and dirty black by reflected light, the precipitate is soluble in dilute nitric acid the solution being light sherry coloured by reflected and transmitted light. 2. Tincture of perchloride of iron gives similar reactions except that a light sherry colour takes the place of the green colour, some flaky deposit (dillenic acid) appears to be undissolved in both cases on adding nitric acid 3 Silver nitrate gives a dirty brown precipitate sulphiding very speedily, insoluble in dilute nitric acid but readily soluble in ammonia. 4 Silver stains on linen (recent) or on the fingers readily clear up on treatment with dillenate of *soda or ammonia and free ammonia 5 Dillenic acid dis*solves sodium bicarbonate with effervescence, the salt is lighter in colour than the ammonium or potassium salts Lead precipitates dillenic acid partially in a neutral solution or one containing a vegetable acid only and precipitates it completely in an alkaline solution The precipitate formed with alum may be washed, it has faint astringent properties *Lime water precipitates it completely if in excess* or in presence of an alkali and acetic acid redissolves the precipitate A potassium salt gives a precipitate (*a*) with acetic acid, the filtrate from (*a*) gives a further precipitate (*b*) with nitric acid and the filtrate from (*b*) gives with alum a precipitate (*c*) which is much less bulky than that obtained with acetic acid Dillenic acid seems to nullify guaiacum colouration of potato and gives no precipitate with the reagents for alkaloids The aqueous solution of the acid or of an alkaline salt keeps well (antiseptic) It is very insoluble in rectified spirit and entirely so in chloroform An earthworm placed in a very weak solution gave two or three convulsive tremors of its longitudinal muscles and died presenting a flattened appearance before and after death Possibly the substance may be valuable as a germicide In the human subject given internally in doses of less than one grain of the dried substance it causes slight griping, nausea at the throat and salivation with black motions (liver stimulation) There is no irritant effect and the taste is if anything pleasant and sweetish Lime water is a speedy antidote Dillenate of zinc may be used as a dressing

Stephenic acid like carminic acid is insoluble in water When washed it sinks as a granular precipitate and *yields* with ammonia stephenate of ammonium having the colour of carminate of ammonium The ammonium salt stains nuclei a beautiful rose colour which will not wash out like *carmine and may be mounted in dammar, glycerine dis*solves it so slightly that specimens stained with it may be mounted in this medium Stephenic acid after drying is more difficult to dissolve than when it is freshly prepared The ash of the plant consists chiefly of alumina, silica and iron

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

NOTE ON THE RETARDED PULSE WAVE IN AORTIC REGURGITATION

BY WALTER BROADBENT, M A, M D CANTAB, M R C P LOND M R C S ENG,

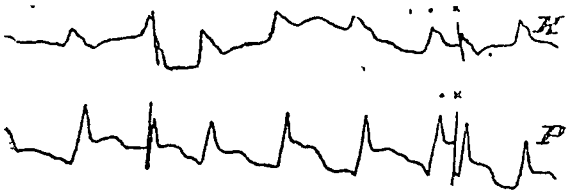
ASSISTANT PHYSICIAN TO THE SUSSEX COUNTY HOSPITAL.

THE accompanying four tracings were taken with an instrument of precision Mackenzie's cardiograph, attached to a Dudgeon's sphygmograph and go to prove Sir William H Broadbent's contention that the pulse in aortic regurgitation is more delayed the greater the regurgitation The first tracing was from a normal heart and pulse to show the usual delay, the pulse being 80 to the minute The second was from a case of slight aortic regurgitation with very little hypertrophy and a good second sound in the neck, though the diastolic murmur in the chest was very loud This showed no more delay than in the normal heart. The pulse rate was 60 The third was from a case of very marked aortic regurgitation with a large collapsing artery The apex beat was in the seventh space, four inches below and two inches outside the nipple, no second sound was audible in the neck The diastolic murmur over the aortic and pulmonic areas was much less loud than in the last case To the hand and in the trac

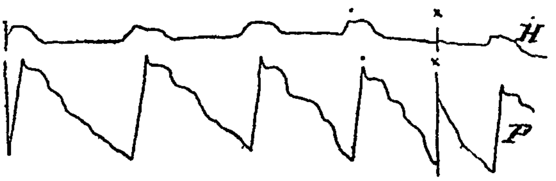
to be synchronous but the

between the carotid and the p

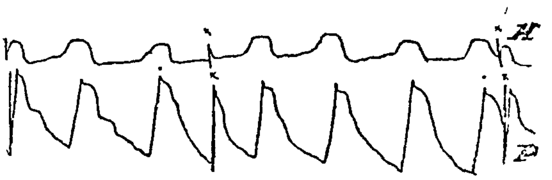
pulse was a whole interval behind the heart and the pulse rate being 80 the delay works out at about 0 75 seconds The delay between the apex beat and the carotid throb and between the carotid throb and the radial pulse were both appreciable to the finger The interval between the carotid and radial pulses was decidedly longer than with a normal heart, but that between the apex beat and the carotid was so marked that it raises the question, most difficult to decide, how late in the cardiac systole does the pulse wave start from the heart when the aortic valves are practically absent?



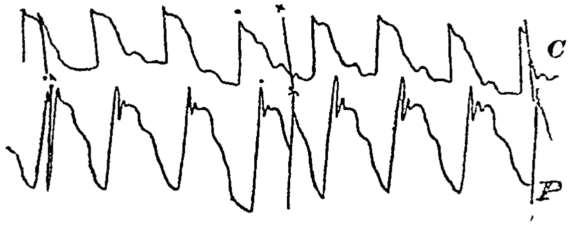
Normal.



Slight aortic regurgitation.



Severe aortic regurgitation.



Carotid and pulse; severe aortic regurgitation.

Brighton.

MICROSCOPICAL OBSERVATION OF THE GLYCOGEN REACTION.

BY DR. GIUSEPPE SPEZIA.

IN attempting to explain the biological significance of the glycogen reaction and to account for the presence of glycogen in the white corpuscles of the blood the following experimentally ascertained facts must be kept in mind. As I have already mentioned in THE LANCET of March 7th, 1903, p. 655, I found that the glycogen reaction could be produced by means of subcutaneous injections of fats (olive oil or hog's lard), albuminoids (peptone), and carbohydrates (glucose). The presence of glucose and peptone in the blood is proved by the phenomena of glycosuria and peptonuria. I have found that not only has glycogen a positive chemiotaxic action but also that peptone and glucose have it. Moreover the white corpuscles drawn into the capillary glass tubes used in the experiments on chemiotaxis and filled with solution of peptone presented the glycogen reaction, whereas the white corpuscles *in the blood* of the same animals as were employed in the experiments did not present it. These facts prove that the leucocytes contain proteolytic, amylolytic, and lipolytic diastases which enable them to form glycogen from albuminoids, carbohydrates, and fats. It is also known that these latter substances appear in increased amounts in the blood during digestion and in many infectious diseases. Achard and Loeper have stated this with regard to glucose in pneumonia and gastro-intestinal diseases. Becquerel and Rodier have stated it with regard to fats in diseases of the respiratory organs, pneumonia, tuberculosis, and puerperal fever; the occurrence of peptonuria supplies the evidence with regard to albuminoids in pneumonia.

Bearing these facts in mind the glycogen reaction may be easily and with much probability explained as a manifestation of the process by which certain substances abnormally abundant in the blood are converted into glycogen by the action of the polynuclear leucocytes. The hyperleucocytosis which according to my clinical observations accompanies the glycogen reaction may be similarly explained, because these substances have a positive chemiotaxic action. The hyperleucocytosis of infectious diseases is not the first sign of resistance to pathogenic agencies exhibited by the organism. The first sign of this kind is a chemical one characterised by the appearance of the above-mentioned substances in the blood. Hyperleucocytosis is therefore based upon chemical facts.

The glycogen reaction is of practical value from a clinical point of view, for the tests which give it are easily and quickly applied and when the reaction is obtained it points to the existence of hyperleucocytosis. In the contrary event, however—namely, when the reaction is not obtained—I hardly think that the present state of knowledge would justify the inference that there is no hyperleucocytosis.

Turin.

ABDOMINAL PAIN AS A SYMPTOM IN ACUTE LOBAR PNEUMONIA.

BY J. RAESIDE SMITH, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.,

LATE HOUSE PHYSICIAN AND HOUSE SURGEON AT THE INGHAM INFIRMARY AND WESTOE DISPENSARY, SOUTH SHIELDS.

DURING the last few months several cases of acute lobar pneumonia have come under my observation. In all of these among the initial symptoms was one which is not too strongly emphasised in our text-books—namely, acute abdominal pain. In each case the signs and symptoms were typical of acute lobar pneumonia. I may state that in two of these cases morphia had to be administered subcutaneously on account of the severity of the symptom.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Prooemium.

LONDON TEMPERANCE HOSPITAL.

THREE CASES OF UNUSUAL HERNIA; HERNIOTOMY; RECOVERY.

(Under the care of Sir WILLIAM J. COLLINS.)

FOR the notes of the cases we are indebted to Mr. J. S. Hosford, surgical registrar.

CASE 1. *Richter's hernia.*—A single woman, aged 48 years, was admitted into the London Temperance Hospital on Nov. 12th, 1902, complaining that she had had a lump in the right groin for a year but that four days previous to admission the lump became larger and she had suffered from vomiting and had passed neither fæces nor flatus. Her general condition was good but there were considerable abdominal distension and tenderness and some redness over the swelling in the right groin, which was of the size of a golf ball and was dull and devoid of impulse. An enema brought no motion away. At 1.45 A.M. on the 13th Sir W. Collins under chloroform cut down on the swelling in the right groin. On opening the sac a considerable quantity of sanious but odourless fluid escaped. It was clear that a portion only of the circumference of the small intestine was external to the femoral ring but acutely strangulated. Sir W. Collins divided Gimbernat's and Poupart's ligaments and freely exposed the whole knuckle of intestine, a portion of which was nipped. About one-third of the circumference of the gut appeared to be involved and this was of a dusky purple tint and covered with a little flaky lymph It was sharply differentiated *from the rest by a grey line of strangulation It was* therefore deemed prudent not to return the damaged gut freely into the peritoneal cavity, but a ring of sutures was passed through the peritoneal and muscular layers of the adjacent healthy portion and the surrounding ligaments and fascia, so as to make the area *formerly strangulated face the* external wound The latter was left open and lightly packed with iodoform gauze Flatus was passed per rectum on the 14th and the general condition was good On the 16th some fæcal staining was noticed on the dressing and for a week *some fæcal matter escaped from the groin, though full* motions were passed per rectum The intestinal wound closed in a few days and the gut was drawn inwards by peristalsis, though retaining a ring of adhesions along the sutured line, *thus causing a puckering of the external wound, which closed completely by Jan 2nd, 1903 The patient was discharged* passing normal motions and with no hernia

CASE 2 *Piece of bone transfixing a hernial sac, simulating strangulated hernia* —A married woman, aged 64 years a multipara, had been ruptured for 44 years On Feb 26th, 1903, *she was "taken suddenly' with pains in the abdomen* and the seat of the old rupture—the left groin—became exceedingly tender, and she could not put back the hernia as she generally could She sent for a medical man who "tried to put it back for three days' and she was then *admitted to the London Temperance Hospital Her general* condition was not at all bad, but she had been frequently sick and the bowels had not acted for several days, though *an enema brought away scybala There was on admission* a smooth elastic swelling in the region of and resembling a *small femoral hernia It was irreducible and gave no* impulse but was excessively tender to handle and the left inguinal region of the abdomen was also very tender to the touch Sir W Collins advised operation and under chloroform he cut down and exposed the sac of *what appeared to be a hernia On passing the finger over* the surface of the sac he detected a sharp pointed foreign body On seizing this and withdrawing it it proved to be a piece of bone one and a quarter inches long and varying from an eighth of an inch to a quarter of an inch in width *This piece of bone was transfixing the supposed sac* A probe was passed along the track of the bone and the cavity was cautiously laid open It proved to be, as was suspected a hernial sac communicating through the femoral ring with the general peritoneal cavity, but untenanted There was *no evidence of any recent perforation of gut and how the* piece of bone, which was thought to be a rabbit bone, had *been deposited in and made to transfix, the sac could only be* a matter of conjecture The sac was removed, the wound was sewn up, and healing took place per primam A little cystitis troubled the patient for a day or two during convalescence but she was quite well and was discharged on March 27th

CASE 3 *Richter's hernia* —A married woman, aged 45 years, had suffered from hernia for five years She was seized on Feb 20th, 1903 with sudden and severe abdominal pain and she vomited. The bowels were constipated On the 22nd she was admitted to the London Temperance Hospital There was then a tense, tender, irreducible swelling in the left femoral region Sir W Collins decided to operate at once and under chloroform exposure of the sac showed this to have been ruptured some sanious fluid escaping A portion of small intestine was tightly strangulated in the femoral ring A director was with some difficulty and with great care inserted under Poupart's ligament and the latter was freely divided It was then seen that only a portion of the enteric cylinder was involved The strangulated portion was purple in colour and œdematous and was defined by a greyish line from the unsnared portion Sutures passed through the outer coats of the sound gut were employed to fix it to the surrounding ligaments and *fascia so as to leave the engaged intestinal area facing* the surface and excluded from the peritoneal cavity The gut was well greased [illegible] left open, lightly pack [illegible] but uncomplicated. [illegible] gut occurred. *The stitches were removed on March 4th The* site of the wound became puckered during cicatrisation as the gut, resuming its duties, became drawn up into *the abdomen, though doubtless leaving an adhesion around* the femoral ring The patient was discharged well on March 26th

---

WESTERN INFIRMARY, GLASGOW

NOTES OF SOME SURGICAL CASES

(Under the care of Dr J CRAWFORD RENTON)

FOR the notes of the cases we are indebted to Dr G Rutherford Jeffrey

CASE 1 *Rupture of the kidney, nephrectomy* —The patient, a man, was admitted to the Western Infirmary, Glasgow, having fallen down the hold of a ship and sustained a severe injury in the right lumbar region The pain was intense over the right kidney and his pulse was feeble In a few hours he had rallied from the shock and passed a considerable quantity of bloody urine The blood gradually disappeared and the temperature and pulse continued normal until the morning of the tenth day when he was seized with sudden hæmorrhage from the bladder without apparent cause and profound collapse Dr Jeffrey saw him at once and injected saline solution into both axillæ and at 9 15 A M , shortly before which time the hæmorrhage had taken place, the kidney was exposed and removed It was almost split in two and lacerated and the amount of hæmorrhage round about it was considerable Its pedicle was tied with silk and it was grasped in addition with a curved metal clamp, this being removed in four days He progressed favourably until the eighth day, when his temperature rose to 104° F and it was quite evident that there were still some clots in the bladder, as shown by the fact that he was passing a small amount of blood in the urine In these circumstances suprapubic cystotomy was performed and the bladder was washed out. He *progressed favourably and* is now quite well and is passing 46 ounces of urine daily

CASE 2 *Nephrectomy for calculous pyelitis* —Dr R. Jardine sent a married woman, from whose left kidney a stone was removed by Dr Renton three years ago from which operation she completely recovered, a year afterwards had again a small calculus removed and as she still continued to suffer from the chronic pyelitic condition which is induced by calculi at her earnest request her kidney was removed , it contained several other calculi She progressed favourably and is now quite well

CASE 3 *Nephro lithotomy* —The patient, a male, was admitted into the Western Infirmary, Glasgow, with a history of left renal colic which had occurred on several occasions during the last three years He had been under the care of Dr R. Spence of Burntisland and latterly was seen by Dr W F Somerville who sent him to the infirmary *on account of urgent pain He had never passed blood in* his urine. A Roentgen ray photograph showed the distinct outline of a calculus in the substance of the kidney Nephrotomy was therefore performed and the calculus was *removed Only a tiny portion of* it protruded into the pelvis of the kidney and the rest had to be enucleated out of its substance

CASE 4 *Osteotomy for faulty ankylosis* —A boy, aged 15 years, was sent by Dr A N Montgomery with his knee joint ankylosed at a right angle This had existed for several years A wedge of bone was removed from the knee and the limb was straightened Union in a straight position was complete and the patient now walks about with an O Connor extension boot, requiring neither crutch nor stick to assist him although his right leg is six inches shorter than the other

CASE 5 *Three operations for intestinal obstruction in the same patient* —The patient, a male, was operated on in [illegible] and a month [illegible] to a band [illegible] the ileum. Studded over the peritoneum were a large number of tuberculous nodules He recovered and went home. In October, 1902, Dr T McG Fletcher telephoned that he was again suffering from obstruction and on opening his abdomen a coil of bowel tightly constricted was found , the adhesions were divided and from this he recovered The tubercle had disappeared A fortnight after he was again seized *with symptoms of obstruction due to a portion of bowel* being constricted and gangrenous; this was removed and he left the infirmary quite well, having been operated on three times for obstruction of the bowels, a very uncommon experience.

CASE 6. *Burst appendix and intestinal obstruction.*—A girl, aged 12 years, was sent by Dr. W. Duff of Wishaw to have her appendix removed. The night after she arrived she was seized with symptoms of rupture of the appendix which was at once removed. Ten days afterwards she had an attack of acute obstruction due to a portion of bowel being constricted by a band; this was divided and she recovered. She had previously had three attacks of appendicitis.

CASE 7. *Paralysis of the face; operation; recovery.*—A girl, aged 14 years, was sent by Dr. A. McLelland of Alexandria, Dumbartonshire, with a history of discharge from the ear for three and a half years and of paralysis of one side of the face for three years, tenderness over the mastoid region, and with an increased pulse-rate and temperature. The patient was somewhat drowsy. The mastoid antrum was opened and pus was evacuated. When the acute symptoms subsided the mastoid and tympanum were converted into one cavity, according to the method recommended by Mr. C. A. Ballance, and when covered by granulation tissue skin grafts were applied to effect complete healing and cessation of discharge. A month after the operation the paralysis had completely disappeared and the patient was using her muscles the same as formerly.

Remarks by Dr. RENTON.—Case 1 is of interest as illustrating the fact that a badly ruptured kidney may improve temporarily and then have a recurrence of hæmorrhage. When such does happen the only chance for the patient is operation. Case 5 is interesting as showing the complete disappearance of the tuberculous nodules noted at the first operation. Case 6 and several others seem to illustrate the importance of operating after one attack in suitable cases, as every recurrence means additional adhesions being formed and greater danger of obstruction taking place. Case 7 is a striking illustration of how quickly muscles which have been paralysed for three years recover. No electricity was employed to effect this, so that the benefit must be entirely ascribed to the facial nerve being relieved from inflammatory pressure caused by the chronic inflammation in the tympanum.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Multiple Aneurysms of the Splenic Artery associated with Calcification of the Portal Vein.—Primary Sarcoma of the Heart.—Acute Leukæmia with a Scheme of Classification of Leukæmias and Pseudo-leukæmias.—A New Method of Blood-counting.—Cirrhosis of the Liver in an Infant.—Plexiform Neuroma of the Orbit.

A MEETING of this society was held on May 19th, Mr. R. J. GODLEE, Vice-President, being in the chair.

Dr. R. S. TREVOR showed a specimen of Multiple Aneurysms of the Splenic Artery associated with Calcification and Dilatation of the Portal, Splenic, and Mesenteric Veins. The specimen was found post mortem in the body of a man, aged 53 years, who died from loss of blood consequent upon ulceration of the bowel. The man had been admitted into St. George's Hospital for the radical cure of an old hydrocele and no disease was suspected until the operation was performed, when a great tendency to hæmorrhage was noticed. On the following day much enlargement of the spleen was detected and the edge of the liver was felt below the costal margin. At the necropsy, in addition to the condition of the splenic vessels, a very large spleen and a cirrhotic liver were found together with signs of old syphilis. After discussing the relationship of chronic adhesive pylephlebitis to cirrhosis of the liver, Dr. Trevor stated that the vascular disease and the cirrhosis might be explained as the indirect result of a syphilitic toxin. At the same time it was thought that in spite of the absence of a blood examination there was much to be said in favour of the case having been one of Banti's disease implanted on a syphilitic soil. The tendency to hæmorrhage, the large spleen which weighed more than the liver, and the wide meshed cirrhosis formed by narrow bands of fibrous tissue, as well as the histological appearances of the spleen and the chronic endophlebitis of the splenic and portal veins, all agreed with Banti's description. The aneurysms on the splenic artery were the outcome of a syphilitic degeneration affecting the vessel in its least supported area.

Dr. J. H. DRYSDALE read an account of a case of a woman, aged 43 years, who died from Sarcoma of the Heart. She had had an attack of rheumatism 15 years previously and since her last confinement, about 14 days before admission to hospital, her general condition had become bad. When admitted she was collapsed and breathing was difficult. The heart sounds were irregular and feeble but no murmur was detected. She died three days after admission. At the necropsy the two layers of the pericardium were everywhere adherent but could be easily separated. At the root of the aorta there was a distinct mass of whitish new growth. The parietal pericardial layer was everywhere infiltrated and in places it was nearly a quarter of an inch thick. The muscular walls of all four chambers were infiltrated with new growth. The aorta and pulmonary arteries were surrounded by new growth. Microscopical examination showed the growth to be a sarcoma. In the section of the pericardium the growth had an alveolar structure but this was due to the nature of the tissue infiltrated as the appearance was quite absent in the growth which occurred in the glands and the lung. Dr. Drysdale considered it impossible to be certain where the growth originated, whether in the heart or the pericardium, but the mass in the wall of the right ventricle and ventricular septum was the largest and probably the primary growth.—Dr. H. M. FLETCHER asked if any reference to specimens of a similar nature had been found. He considered that the specimen was one of extreme rarity. He thought that the growth probably arose from the visceral pericardium and the structure of the growth resembled an endothelioma rather than a sarcoma.—Dr. DRYSDALE replied that he did not consider that the growth resembled in structure that seen in endothelioma and he was of opinion that it was a primary sarcoma originating in the walls of the heart.

Dr. F. PARKES WEBER read a paper on a case of Acute Leukæmia and on the Classification of Leukæmias and Pseudo-leukæmias. A very anæmic man, aged 49 years, with a purpuric eruption, swollen gums and tonsils, and enlargement of the spleen, liver, and all the lymphatic glands, was admitted into hospital in a semi-delirious condition with slight fever. He died on the following day, about two months from the commencement of his illness. The blood in the heart after death had a peculiar brownish-pink appearance as if mixed with milk and showed an enormous proportion of white cells of which 92·7 per cent. were large or small lymphocytes. The bone marrow in the shafts of the long bones had a creamy brownish-red colour. Microscopical examination of the bone marrow, spleen, lymphatic glands, liver, and of a whitish patch in one kidney showed that all these tissues were permeated with colourless cells, most of them of the lymphocyte 'class' but many of them containing granules (more or less eosinophile) and apparently belonging to the myelocyte class. Dr. Parkes Weber preferred the hyperplasia-like tumour-formation theory of leukæmias. He regarded "acute leukæmia" as a more primitive or less differentiated type of disease than the more chronic forms of lymphatic leukæmia, but doubtless there was no hard-and-fast line to be drawn between them. Microbic infection was often a complication. Typical "spleno-medullary leukæmia" was probably the "most highly differentiated" form of leukæmia. Mere "mechanical" theories (cells overflowing or being squeezed out into the blood stream) were insufficient to account for the differences between leukæmias and pseudo-leukæmias.

Dr. W. M. STRONG and Dr. C. G. SELIGMANN communicated a note on a New Method of Counting the Corpuscles of the Blood. They stated that by the following method they had been able to obtain permanent preparations from which the number of red and white cells could be counted at any period subsequent to the time at which the blood was taken, while the use of any form of counting chamber was done away with. Five cubic millimetres of blood were diluted a hundred-fold with a fixing solution containing methyl violet. For the white cell count five cubic millimetres of this mixture were blown on to a slide from a pipette graduated to deliver this quantity. The drop was allowed to dry and was mounted in Canada balsam in the usual way. When such slides were examined with a $\frac{1}{6}$-inch objective the white cells were seen to be stained a conspicuous blue among the unstained red corpuscles. The former were counted by going over the whole of the dried-up drop with the aid of a mechanical stage. Then knowing the dilution of the blood the number of white cells per cubic millimetre could be readily calculated. For the red cell count a further dilution of the first hundred-fold dilution was made into a solution containing eosin. Five cubic millimetres of this were placed on a slide, dried, and mounted in Canada balsam From the total number of red cells present in the film formed by the dried-up drop the total number of red cells per cubic millimetre was calculated. Dr. Strong and Dr. Seligmann stated that as the outcome of considerable experience in the clinical laboratory of St. Thomas's Hospital, where the method had for some time been in daily use, the results obtained by this method did not differ appreciably from, nor take longer in obtaining than, those given by counting with a Thoma Zeiss slide.

Mr. L S. DUDGEON read an account of a case of Enlargement of the Liver in a child, aged nine months, who died after four days' illness from broncho-pneumonia. The temperature was subnormal (from 84° to 94° F.) during the illness. There were well-marked evidence of rickets and enlargement of the liver but no jaundice. The kidneys were normal. No other abnormal changes were manifest. The liver was very firm, yellow-coloured, with white patches through its substance. Large areas of fibrous tissue having a unilobular distribution were present in the bile-ducts in large numbers. Dr. H. D. Rolleston considered the specimen to be one of congenital cystic disease of the liver.—Dr. H. BATTY SHAW quoted the case of a child who was subject to periodic rises of temperature and was also anæmic. One week before death the child developed ascites and œdema of the legs. At the necropsy the liver did not appear to be abnormal but on microscopical examination the specimen exhibited the same appearances as those shown by the specimen exhibited by Mr. Dudgeon.—Dr. W. S. LAZARUS-BARLOW said that he had seen a similar specimen and believed it to be congenital cystic disease of the liver; the absence of congenital cystic disease of the kidneys did not negative the fact that the specimen was one of congenital cystic disease. He suggested that congenital cystic disease of the liver was a special form of adenoma of the liver.—Dr. PARKES WEBER thought that it was generally recognised that congenital cystic disease was a special form of adenoma.

Mr. J. HERBERT PARSONS and Dr. W. C. ROCKLIFFE reported a case of Plexiform Neuroma (Elephantiasis Neuromatodes) of the Orbit. The child, aged two years, was shown at a meeting of the Ophthalmological Society in 1899 as a case of pulsating exophthalmos. The proptosis increased gradually without much affecting the child's general health, but finally interference became necessary and Dr. Rockliffe exenterated the orbit in January, 1903, after tying the carotid artery. The child died very shortly after the operation. At the post-mortem examination it was found that the roof of the orbit had been absorbed and that the growth had become intracranial, leading to great distortion of the bony and soft parts. On microscopical examination it was found to consist of convoluted hypertrophied nerves imbedded in dense fibrous tissue. These filled the orbit, extending backwards into the skull and forwards into the posterior part of the upper lid, leading to ectropion. Cases of elephantiasis neuromatodes involving the upper lid and temporal region formed a large proportion of cases of the disease but affection of the orbit was rare and this was the most extensive case on record.

DERMATOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on May 18th, Mr. Malcolm A. Morris being in the chair.—Dr. E [illegible] 1. A case of possible Pemphig[illegible] was a young woman who had be[illegible] Hospital in August, 1902, for a [illegible] the skin and mucous membranes. At this time there was no initial lesion but the whole surface was exuding serum. After a few days the skin began to dry up and desquamated very freely. She became [illegible] for a time, but finally [illegible] her return to health was [illegible] and a suppurative tonsillitis. Soon after this another attack of the exfoliative skin eruption occurred, but on the subsidence of this she was well enough to be discharged. She attended the out-patient department from this time and occasionally exhibited some small bullæ on the chest, while there was a constant exudation from the axillæ, though true bullæ were never found on them. In April last she was admitted on account of a new attack of the erythematous eruption and was then found to be in a very bad condition. Exfoliation again occurred soon after admission and when brought to the society she showed an extensive peeling of the hands and a little on the face, arms, and legs, which were of a much darker colour than normal. Most of the skin was then healthy and the patient's condition, although very bad, did not seem to be in direct proportion to the severity of the skin lesions. Many of the members considered the case to be more probably erythema scarlatiniforme recidivans. 2. A man suffering from Simultaneous Eruptions of Psoriasis with a Follicular and Ecthymatous Syphilide. 3. A child with Lupus of the Nose and Lichen Scrofulosorum of the Body.—Dr. D. B. Lees (introduced) showed a case of Asphyxia Reticularis Multiplex.—Dr. W. J. Freeman showed a girl suffering from a peculiar Rash on the Ulnar Surfaces of the Forearms and on the Inner Sides of the Thighs. The eruption, which was slowly extending, consisted of large retiform patches made up of slightly infiltrated and scaly papules not unlike those of lichen planus, but differing in their smaller degree of prominence and in their mode of onset. The case had been shown to the society before under the diagnosis of parakeratosis variegata and this diagnosis was accepted by all the members.—Dr. J J. Pringle showed a man with Peculiar Ulcerating Infiltrations on the Face. He was a countryman from Wales and the disease had begun on the right ear in September, 1901. The earlier lesions had been destroyed with caustics but new ones had appeared and he now showed four such growths, on the right cheek and in the centre and on both sides of the chin respectively. The growths appeared to be of a granulomatous nature and on careful examination could be seen to be studded with minute pustules. Dr. Pringle said that he had not yet had the patient under observation long enough to carry out any microscopic examination, but that he considered it not unlikely that the disease might turn out to be a case of blastomycosis —Dr. E. Stainer showed a man suffering from Mycosis Fungoides, who had been brought to the society before, to show the result of x-ray treatment. The exposures and the quality of the tubes used had varied in different cases and some burning had taken place but it was all over at the time of exhibition. It was satisfactory to note that in every instance the exposures had been followed by complete disappearance of the tumours, so that for the time, at any rate, the man apparently was free from the disease.—Dr. J. Galloway showed: 1. A patient with a Marginate Erythematous Eruption covering the trunk and limbs and having a fine vesicular edge, while the centre, where resolution had taken place, was marked by deep pigmentation. The patient had been seen previously with an eruption indistinguishable from an ordinary pemphigus and partly on this account and partly from the course of the eruption he made the diagnosis of dermatitis herpetiformis. 2 A case of Exuberant Papillomatous Syphilide.—Dr. J. H. Stowers showed: 1. A woman with Paget's Disease of the Nipple whom he had brought to the society before on account of the long duration (15 years) without the complication of malignant disease of the breast. Carcinomatous nodules had now within the last 12 months developed in the breast and the axillary glands had become infected. 2. A boy, aged 15 years, with well-marked Herpes Iris from which he had suffered several times a year for nine years.—Dr. J. H. Sequeira showed a girl who had a deeply seated Linear Eruption running round and just beneath the horizontal ramus of the right side of the jaw. The history pointed to its resulting from trauma at nine years of age from which it slowly spread, but there was reason to doubt its being lupus. The alternative diagnosis offered was a nævoid growth.—Dr. H. Radcliffe Crocker showed a female patient suffering from Mild Pityriasis Rubra Pilaris, together with a drawing showing her previous condition.—Dr. A Whitfield showed a man suffering from Multiple Tuberculous Affections of the Skin and Eyes. The patient had had a sharp febrile attack in August, 1902, and shortly after had noticed two patches on his face, on the upper lip and chin respectively. Soon after he had trouble with his eyes and this was found to be tuberculous iritis. When exhibited he showed two patches of lupus on the upper and lower lip and very numerous nodules of erythema induratum on the fronts and backs of both legs. The face was being treated by "the light" and the legs by ointment and bandaging. The eyes were reported to have almost returned to the normal and the other lesions were slowly improving.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.—A meeting of this society was held on May 2nd in the Medical Institution, Liverpool. Mr. C. A. Ballance, vice-president, took the chair for the first half of the meeting and then vacated it in favour of Dr. H. E. Jones.—Professor Andrew M. Paterson described the Development and Morphology of the Temporal Bone together with the Mode of Evolution of the Ear. First there was an invagination of the surface epiblast connected with the brain and communicating with the surface (elasmobranchs) Then there was a complete severance of connexion with the surface (bony fishes); then there was the formation of tympanic cavity, membrana tympani, stapes, and columella (reptiles and birds); then there was the addition of branchial elements, malleus and incus, external meatus, and pinna (mammals). The complexity and interest of this evolution were increased by the occurrence of the mastoid antrum, the mastoid process, and the cells. The spiral cochlea of mammals presented an obscure and interesting question. The branchial apparatus took a very secondary share in the formation of the ear and this only in mammals.—Dr. Herbert Tilley cited a case in which a temporal bone seemed to have no mastoid antrum.—Dr. Alfred W. Campbell read a paper on the Cortical Centre of the Auditory Nerve. He stated that in a suitably stained section taken from the middle of the temporal lobe of the brain three definite types of cortical structure might be observed and by careful study of these in successive series it was possible to define with absolute exactitude two definite areas—namely (1) the transverse temporal gyri of Heschl and (2) the posterior three-fifths of the superior temporal convolution. From anatomical, embryological, experimental, and clinico-pathological data he believed that the first area represented the arrival platform for the primary reception of auditory stimuli, while the second represented that part of the cortex which interpreted and elaborated these stimuli. Histological, developmental, and clinico-pathological facts were adduced in favour of these areas having the functions assigned to them. The fact that a lesion in the left hemisphere did not produce complete "word-deafness" seemed to show that the right hemisphere shared the function but to a less degree. Dr. Campbell's histological researches showed no differences between the auditory areas in the two hemispheres and hence he could say nothing about the exact localisation of a "word-hearing" centre.—Dr. Jones read a paper in which he pointed out various relationships of the facial nerve which would enable a surgeon to avoid injuring this nerve during an operation and this without having recourse to any of the numerous measurements which had been laid down from time to time and which were of little value when once an operation had been commenced and landmarks were thereby destroyed.—Mr. A. H. Cheatle read a paper on Quinine Deafness and its Prevention. He said that anæmia was probably the pathological cause of the deafness produced by overdoses of quinine. Once established the deafness was permanent and without remedy; hence the treatment must be preventive. Medical men and others, especially in malarial regions, should be warned of the evil effect which large doses of quinine might have upon the hearing. When quinine was given it should be guarded by full doses of hydrobromic acid.—Dr. Thomas Barr said that he thought that the effect of quinine was especially marked in people whose hearing was already deficient.—Dr. William Milligan said that he had found nitrites of use in the treatment of quinine deafness probably on account of their relieving the anæmia.—Dr. J. Dundas Grant said that he believed that the evil effects of quinine were due to congestion —Mr. C. G. Lee showed a case of Extradural Abscess following Acute Otitis Media. The radical operation was done with complete success and one drachm of pus was evacuated from an extradural abscess in the middle cerebral fossa. Convalescence was retarded by an attack of erysipelas but the patient made a complete recovery.—Dr. Milligan showed a case in which eight days after radical operation had been performed for the cure of chronic suppurative otorrhea skin grafting was carried out, but no packing had been used and yet a perfect result had been produced. He also showed a second case in which the antro-tympanic cavity had been packed for five weeks after the complete operation. An equally successful result had been obtained.—Other cases and a variety of specimens were shown by Dr. William Permewan, Mr. E. M. Stockdale, Dr. Philip Nelson, and Dr. Jones.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on May 7th, Dr. W. Winslow Hall, the President, being in the chair.—Mr. T. Crisp English read a paper on Some Points in the Diagnosis of Acute Abdominal Cases. Attention was drawn to a stage occurring shortly after the onset and marked by the diminution or cessation of all acute symptoms. If, as frequently happened, the patient was first seen during this quiescent period a serious view might not be taken of the case and fatal delay might follow. The effect of stimulants in producing temporary improvement in the patient's condition and in masking the symptoms was pointed out, the action of morphia in this respect being universally known. Large doses of brandy and strychnine intensified the quiescence of symptoms after recovery from the initial shock. Quickness of the pulse, associated with a falling or subnormal temperature, was a symptom of special importance. Diminution or absence of liver dulness, as evidence of free gas in the peritoneum, was of most significance when occurring in the mid-axillary line, or when found shortly after the onset of symptoms in a contracted and board-like abdomen. The various conditions giving rise to this sign were discussed. Leucocytosis in the diagnosis of acute peritoneal lesions was of theoretical rather than of practical value and in many cases might be positively misleading. Perforated gastric ulcer or appendicitis was sometimes closely simulated by certain acute symptoms which appeared shortly before the onset of the menstrual period.—Mr. Edmund Owen said that the custom of admitting cases of intestinal obstruction into the medical wards of hospitals as a matter of course was now happily dying out and physicians were becoming more ready to call in surgical aid. All hernial orifices ought to be examined in cases of abdominal obstruction.—Dr. Sidney P. Phillips mentioned several conditions which simulated intra-abdominal disease.—Mr. P. L. Daniel read a paper on Gastro-enteritis of Obscure Origin simulating, and surgically treated as, Peritonitis. He said that enteritis with or without gastritis might in adults produce such intense collapse, with abdominal symptoms but without diarrhœa, as to suggest peritonitis and to cause operations to be performed for the relief of supposed perforation. He read notes of three cases, on two of which laparotomy was performed, while the third patient died 24 hours after the onset of the symptoms; he also read the post-mortem record of the two fatal cases. The lesions in these patients were those of acute gastro-enteritis, the origin of the process in one case seeming to be a septic state of the gums. He thought that the condition was due not to the bacillus coli communis nor to the bacillus enteritidis but to micrococci introduced from above—namely, from the mouth, nose, middle ear, or œsophagus. The misleading feature in these cases was undoubtedly the absence of diarrhœa. The diagnosis was rendered possible by the history of chronic gastric trouble and by the following facts: (1) the presence of some focus of suppuration in the upper alimentary or respiratory tract; (2) the presence of distressing thirst; (3) the great amount of mucus in the vomit and the not infrequent presence of blood; (4) the presence of marked hyperæsthesia in the epigastrium and about the umbilicus without proportionate pain on deep palpation; (5) the absence of muscular rigidity in the abdominal wall; (6) the absence of the characteristic facies and attitude of peritonism; and (7) the fact that the intestinal obstruction which was simulated was not absolute. The treatment suggested was: (1) the removal of any suppurating and septic foci; (2) the administration of large quantities of bland fluid such as egg albumin or barley water, but not milk; and (3) the subcutaneous injection of two pints of 2 per cent. glucose solution if the collapse did not pass off with the usual remedies.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—A general meeting of this society was held on May 8th, Dr. V. H. Wyatt Wingrave, the President, being in the chair.—Mr. W. J. Chichele Nourse showed a case of old-standing Lupus of the Larynx which had required tracheotomy in an elderly woman.—Dr. W. Jobson Horne inquired if in this patient there were any evidences of tuberculous disease in the lungs or elsewhere and Mr. Nourse replied in the negative.—Mr. Nourse also showed a case of Tertiary Syphilis of the Larynx in a managed 51 years. Treatment on the usual lines had resulted in a very satisfactory recovery.—The President congratulated Mr. Nourse on the quick response to treatment in this case.—Mr. E. D. Vinrace remarked on the very complete recovery obtained.—The President showed a case of Lupus of the Nose, Palate, and Larynx in a girl.—Dr. W. H. Kelson showed a case of Laryngeal Fistula.—Mr. Vinrace remarked that in this case the arytænoid eminences when viewed directly through the fistula were really larger than they appeared to be in the mirror.—Mr. Nourse showed a case of New Growth on the Nose externally presenting an unusual structure.—The President (who exhibited a microscopical specimen of the growth) regarded this growth as extremely rare pathologically. It might be described as a "papillary adenoma," innocent in its nature, and originating probably in the duct of a sweat gland or an aberrant "rest."—The President showed: (1) specimens illustrating the Histology of the Accessory Sinuses; and (2) a specimen of Ceruminous Gland of the External Auditory Meatus.—Dr. Horne showed macroscopical and microscopical preparations illustrating Endotheliomata of the Upper Air Passages.—Dr. J. Dundas Grant inquired of Dr. Horne the clinical appearances of one of the growths shown which had affected the larynx and its duration.—Dr. Horne, in reply, stated that this particular growth had existed for over two years and that in appearance it was a fungating, breaking-down growth like a malignant tumour.—Dr. Kelson asked for a definition of the recently much-used word "endothelioma" and inquired as to the behaviour of such a growth.—Dr. Horne regarded the endothelioma as of local malignancy; it would recur locally if removed.—Dr. L. H. Pegler inquired whether formalin had been used in the preparation of the specimens shown and Dr. Horne replied in the affirmative.—The President remarked about these endotheliomata that some were of rapid growth while others increased but slowly. They were like malignant tumours certainly and were not papillomatous in nature as they grew down deeply into the tissues.—Dr. P. H. Abercrombie showed (for Dr. W. G. Holloway) a case of Hypertrophy of the Lingual Tonsil in a woman, aged 28 years. It was proposed to remove the swollen part with the curved tonsillotome.—Mr. Vinrace and Dr. Horne were against operation in this case as likely to be followed by hæmorrhage.—Dr. Kelson suggested the possibility of a foreign body as a cause for the swelling and redness of the lingual tonsil.—The President and Mr. Nourse joined in the discussion.—Mr. Nourse exhibited (1) a new form of Infundibular Probe and Cannula for the Frontal Sinus; and (2) a Probe and Cannula for the Sphenoidal Sinus.—Mr. Nourse read the notes of the sequel of a case of Gumma of the Larynx shown about a year ago. The patient had died from thoracic aneurysm.—The President described a slight Modification of Moure's Operation applicable to children. The method consisted in the placing of an Adam's clamp in the nostrils after the septal incisions had been made and the deviation had been rectified. The clamp acted as a splint and tended to arrest bleeding.—Dr. Pegler having spoken, the President replied.

Glasgow Northern Medical Society.—This society held its usual monthly meeting on April 7th in the Ophthalmic Institution, Glasgow, Dr. J. S. Muir, the President, being in the chair.—Dr. A. Maitland Ramsay, with the assistance of his staff, gave a series of demonstrations with special reference to Diseased and Injured Conditions of the Eye. As there were several patients present by arrangement these were shown first and their conditions were explained. The first class of cases referred to an operation for ptosis. The operation which had been performed was a modification of that by Mules. The advantage of it was that if it were not successful it could be easily done again and it left very little scar, if any. The upper lid was suspended on a loop of wire which remained permanently in the tissues. The next class of cases calling for attention consisted of three patients for whom paraffin stumps had been supplied after enucleation. The great difficulty with the artificial eye was the sunken, flat, and dead-like appearance of it. The operation described went a good way to overcome that drawback. When liquid paraffin was injected into the capsule of Tenon the artificial globe in front could move about and it was very difficult to detect that it was artificial. Another class of cases of considerable psychological interest was demonstrated in which sight had been restored after many years of more or less total blindness. In one case a dark dislocated lens had been found blocking up the pupil and was removed, after which the patient had good vision. Several preparations, including cultures and microscope slides, were shown demonstrating the bacteriology of the conjunctiva and arranged by Dr. J. C. McClure, bacteriologist to the institution.—The electric room was then inspected where Dr. John Gilchrist explained the various apparatus, including the x-ray appliances.—Dr. Ramsay afterwards delivered a lecture on Iritis in the class-room. The clinical features were illustrated by hand-painted coloured slides, while the pathological aspect was clearly demonstrated by means of microscopic specimens thrown on the screen by the projection microscope. It was thus possible to have two pictures shown at once.

Aberdeen Medico-Chirurgical Society.—A meeting of this society was held on May 7th, Dr. J. Gordon, the President, being in the chair.—The following clinical cases were exhibited:—Dr. J. F. Christie: (1) Two cases (brother and sister) of Ichthyosis; (2) a case of Urticaria Papulosa going on to Prurigo; and (3) Photograph of a peculiar Syphilide.—Dr. J. Marnoch: (1) A patient with Arrested Development of the Mandible; (2) Radical Cure of Inguinal Hernia in a man, aged 73 years; (3) a patient operated on 18 months ago for Chronic Ulcer of the Stomach; (4) a case of Posterior Gastro-enterostomy for Cicatrised Ulcer of the Stomach; and (5) a case of Intra- and Extra-Peritoneal Rupture of the Bladder successfully operated on.—Dr. J. Scott Riddell: (1) A case of Abdominal Tumour, probably lipoma of the omentum; (2) a patient after Removal of Tuberculous Glands from the Mesentery; (3) a patient in whom Burrell's Operation for Recurrent Dislocation of the Shoulder had been performed a year before; (4) a case of Coxa Vara with Skiagram; and (5) a case of Congenital Dislocation of the Hip treated by the method of Lorenz.—Dr. G. Rose: (1) A case of Resection of the Knee-joint; and (2) a case of Acute Diaphysitis of the Femur.

West Kent Medico-Chirurgical Society.—The seventh meeting of the forty-seventh session of this society was held on May 1st, Dr. George Herschell, the President, being in the chair.—In his address from the chair on the subject of the Diagnosis of Cancer of the Stomach in the Early Stage the President, after enumerating the symptoms met with in the early stage of cancer of the stomach, pointed out that none of these were distinctive, although persistent anorexia was a sign which was very often met with. In his opinion the most valuable signs were to be obtained by the examination of tiny fragments of mucous membrane of the stomach procured by Hemmeter's method of curettage of the stomach by means of a rubber stomach tube with unbevelled eyes. The conditions which should make the practitioner suspect malignant disease of the stomach, were the proliferation of epithelial cells through the membrana propria and between the glands, fission of the gland tubules, the atypical shape of the glands, and the presence of cells the nuclei of which were undergoing atypical mitosis.

Plaistow and Canning Town Medical Society.—A meeting of this society was held on April 29th.—
[illegible] the Heart.—Dr. W. M. D.
[illegible] le Abscesses.—Mr. P. Rose
[illegible] an Infant; it weighed 46
[illegible] at as a result of a com-
[illegible] ountry Holiday Fund that
[illegible] small honorarium to the
medical men who undertook the duties of examining the children.—Mr. L. S. Dudgeon, who was present by special invitation, then gave an address on Tuberculosis of the Serous Membranes, dwelling particularly on the conditions of tuberculous pleurisy, tuberculous meningitis, and tuberculous peritonitis.—After a little discussion the meeting terminated with a vote of thanks to Mr. Dudgeon.

Colchester Medical Society.—The spring meeting of this society was held on May 12th, Dr George Brown being in the chair.—The following resolution was carried regarding the late President, Mr. R. F. Symmons.

> This meeting desires to express its heartfelt sorrow at the loss which the society has sustained by the death of Mr. R. F. Symmons who was a member for 42 years. His high sense of honour, his unvarying kindness, and his earnest desire to promote goodwill among his professional brethren were qualities much appreciated by this society.

Dr. W. W. Sinclair of Ipswich showed specimens of Tumours of the Eye.—Dr. Beaumont Percival read a paper on Curettement, its uses.—Dr. B. H. Nicholson showed (1) an Osteoma of the Upper Jaw (the patient was shown); (2) a case of Coxa Vara; (3) a specimen of Gangrenous Appendicitis; and (4) Acute Necrosis of the Diaphysis of the Ulna

Reviews and Notices of Books.

The Blood: How to Examine and Diagnose its Diseases. By ALFRED C. COLES, M.D., B.Sc. of Public Health, Edin. Second edition. With six Coloured Plates. London: J. and A. Churchill. 1902. Pp. 286. Price 10*s.* 6*d.*

IN our review of the first edition of this work we explained its object and scope and expressed the favourable opinion which we had formed of it. We may now congratulate the author on the satisfactory reception which his book has met with—a reception which has justified his belief that a small book dealing particularly with the practical methods of, and the clinical deductions to be obtained from, the examination of the blood would prove of service. The importance of the subject is now generally recognised and since the appearance of the first edition much work has been done by many observers with respect to the examination of the blood and the changes in the corpuscular elements in disease. Dr. Coles has taken advantage of such researches and has brought the present edition up to modern requirements by a thorough revision of the work and the addition of much new matter.

The section on Malarial Parasites has received particular attention. Much discussion has taken place concerning the best method suited to the recognition of these organisms. Dr. Coles describes in great detail the technique of a method of examining the blood which he deems best suited to meet the requirements of physicians—viz., a process insuring rapidity and certainty and one which introduces the fewest possible errors. Those practitioners who are likely to be brought into contact with malarial cases will do well to study carefully the pages devoted to this subject, as an examination of the blood is now acknowledged to be of great assistance in doubtful cases.

Dr. Coles also gives directions as regards examining the blood for the embryo filariæ. If permanent preparations are required he advises that a film should be procured which is very thin at one end and moderately thick at the other; this film should be fixed in alcohol and ether and stained with eosin and hæmatoxylin. By this means the internal structure and sheath of the parasite are well shown, and in the thin part of the specimen the nature of the leucocytes can also be ascertained.

Muco-Membranous Entero-Colitis. By MAURICE DE LANGENHAGEN, M.D., Consulting Physician at Plombières, Vosges, France. London: J. and A. Churchill. 1903. Pp. 115. Price 3*s.* 6*d.*

THIS little volume contains a very good description of the disease known as muco-membranous entero-colitis. As the affection has not received the attention which it merits in most medical text-books, Dr. de Langenhagen's remarks will be found very interesting. A clear description is given of the principal symptoms of the disease, of which the three most characteristic are a glairy secretion from the bowels which is more or less formed into pseudo-membranes, the irregularity of the intestinal functions, and abdominal pains of a special character. These phenomena are considered in detail and the reader is presented with a good clinical picture of the malady. Dr. de Langenhagen points out that patients suffering from the disease "never possess what may be called intestinal equilibrium." As a general rule, he says, constipation prevails; in rare cases there exists a true form of diarrhœa which persists throughout the course of the affection. These exceptions, however, do not invalidate the statement that "muco-membranous entero-colitis is an enteritis typified by constipation." Food, however, is often discharged imperfectly digested. Green vegetables such as cabbage and spinach, French beans, green peas, carrots, and those vegetables made into salads are passed almost unchanged in appearance. Fats, too, are hardly ever digested. Upon these indications the treatment is mainly founded. The affection, though prolonged and difficult to control, can always be considerably relieved and sometimes completely cured by therapeutical means chosen with discernment and employed with perseverance. The question of diet is of supreme importance. The problem consists in nourishing the patient in such a way that the stools shall be neither abundant nor irritating. Dr. de Langenhagen's remarks on this part of the subject are very full and lucid and will be found easy to act upon in practice. He naturally lays stress on hydro-therapeutic measures. The regimen which a patient has to follow when placed under proper supervision is of the greatest benefit and excellent results have been obtained.

With regard to the etiology of the disease, Dr. de Langenhagen is of opinion that muco-membranous entero-colitis occurs much more frequently than is generally supposed and he thinks that it should be considered a "constitutional malady." He believes that certain persons are predisposed "to a sort of laxity of the tissues, a sort of weakening of the intestinal parietes," which will very probably lead to intestinal atony and thence to those more characteristic morbid phenomena which constitute the disease. He has also found that most of his patients are of the "neuro-arthritic" diathesis. We can recommend a perusal of this small work to all those who wish for information on the subject with which it is concerned.

Atlas und Grundriss der Krankheiten der Mundhöhle, des Rachens, und der Nase. Von Dr. L. GRÜNWALD in München. Zweite umgearbeitete und erweiterte Auflage. 42 farbige Tafeln und 39 Textabbildungen. (*Atlas and Essentials of Diseases of the Mouth, the Pharynx, and the Nose.* Second edition, completely rewritten and enlarged. 42 coloured plates and 39 illustrations in the text.) Munich: J. F. Lehmann. 1902. Pp. 212. Price 12 marks.

DR. GRÜNWALD intends this book to act as a preparation for the study and digestion of larger and more elaborate scientific works by students and practitioners of general medicine. But, as Dr. Grünwald rightly contends, a general knowledge can alone be obtained by reading; technique and clinical experience can only be attained by work, conscientiously performed, under the direction and supervision of a competent instructor. For this reason the book is not subject to too minute subdivision of its contents. Also but few instruments are depicted, as they can all be seen by reference to instrument makers' catalogues, and in his preface Dr. Grünwald tells his readers the names of the makers of his instruments.

The first 30 coloured plates are representations of pathological conditions, whilst the last 12 are devoted to reproductions of microscopical sections. This proportion appears to us to be injudicious, especially in view of some of the sections chosen for reproduction, several being allotted to the histological appearances of adenoids. The plates illustrating diseased conditions are both well drawn and well coloured, amongst the most interesting being Plate IV., Fig. 2, a very typical example of pyorrhœa alveolaris; Plate VII., Fig. 1, broken-down gumma of the tongue, and Fig. 2, carcinoma of the tongue; Plate VIII., Fig. 3, diphtheria, not by any means a characteristic example; Plate XII., Fig. 1, an extremely good drawing of carcinoma of the tonsil; Plate XXV., tertiary syphilis of the nasopharynx; and Plate XXVI., hypertrophies of the posterior extremities of the inferior turbinate body, &c.

Dr. Grünwald devotes but little space to a description of the anatomy and physiology of the parts—only 17 pages; he, however, gives quite sufficient to enable his readers to follow any subsequent remarks which touch upon them. He then considers the question of general pathology and examination of the patient with a brief outline of the more usual intra-nasal operations and their indications and he concludes this part with general rules for the guidance of the operator. All acute inflammatory states are taken in sequence, commencing with simple catarrh, the same method being followed in chronic inflammations and specific conditions; also new growths, paralyses, &c., are shortly and clearly reviewed.

Dr. Grünwald is so well known that it is needless to say more than that the book contains a brief summary of the theories and principles so ably advocated by himself, one of the pioneers of nasal surgery. We have no doubt that to those acquainted with the German language this little book will be found useful and instructive. It has the merit of individuality and is devoid of any element of uncertainty in the advice given as to treatment.

LIBRARY TABLE.

First Aid to the Injured and Sick. By F. J. WARWICK, M.B. Cantab., M.R.C.S. Eng., and A. C. TUNSTALL, M.D., F.R.C.S. Edin. Bristol: John Wright and Co. London: Simpkin. 1903 Pp. 236. Price 2*s.* 6*d.*—This is the third edition of a useful little work, the first edition of which we reviewed in THE LANCET of March 2nd, 1901, p. 638. The favourable impression which we then formed of the practical part of the book has in no way altered, but we still think that there is a little too much anatomy and physiology for lay readers. We are glad to see that the authors have enlarged their directions on the lines which we suggested as to the method of releasing sufferers from "live" electric wires. That the book has reached a third edition shows that it has been found useful and we daresay that a fourth edition will soon be called for.

London University Guide and Correspondence Calendar, 1902—1903. London: University Correspondence College. Pp. xx. + 64. Gratis.—This calendar will be found of value by students of the University of London. It gives the regulations for the examinations to be held during 1903 and 1904, with notes and instructions as to how a student may best prepare himself for his examinations.

The Medical Annual, 1903. Bristol: John Wright and Co. Pp. 824. Price 7*s.* 6*d.*—The present is the twenty-first annual issue of this valuable compendium. Medicine and the allied sciences have so enormously widened their scope of late years that it is impossible for any medical man to keep himself posted in advances in his art without the aid of a judiciously selected *précis* of knowledge such as the Medical Annual affords. The contributors to the volume now before us number 34 and all of them are experts in the matters upon which they respectively write. Besides the more purely professional subjects of medicine, surgery, and the like, information is given upon legal decisions affecting medical men, inebriate homes, convalescent homes, sanatoriums for tuberculosis, and many other matters about which medical practitioners constantly want to know. The compilation will be found most useful.

The Municipal Year book for 1903.—Edited by ROBERT DONALD. London: Edward Lloyd, Limited. Pp. 690. Price 3*s.* 6*d.*—This is a book which gives a great deal of information about municipal bodies both in the metropolis and the provinces. A *résumé* is given of Acts of Parliament passed during the session of 1902 affecting local government which will be found valuable We suppose that the publisher is responsible for the irritating way in which advertisements are sandwiched into the body of the book and between the table of contents and the index.

JOURNALS AND MAGAZINES.

The Practitioner.—Malignant Diseases of the Mouth form the subject of a "special" May number of the *Practitioner.* The articles therein contained deal almost exclusively with diseases of the tongue, and a very complete account of epithelioma of the tongue with its natural history and its treatment may be gathered from reading the various contributions of Mr. W. Whitehead, Mr. H. T. Butlin, and other surgeons. The comparatively rare condition of sarcoma of the tongue is dealt with by Mr. A. D. Fripp, C.V.O., whose remarks are based on 29 cases. A prominent feature of most of the articles on carcinomatous growths of the tongue is the urgency with which the writers insist upon the frequency of mistake arising from the fact that epithelioma is often super-imposed upon syphilitic conditions. The great care necessary for early diagnosis and the extreme importance of such diagnosis are well illustrated. The article by Mr. Jonathan Hutchinson, jun., is illustrated by some excellent plates.

Quarterly Medical Journal.—The first of the original articles in the May number of this journal is an elaborate argument in favour of the exogenesis of cancer by Dr. A. T. Brand of Driffield. He uses the word "exogenesis" in the sense of infection from without and with regard to the means by which the pathogenic influences obtain access to the patient's system he says that since the favourite site of epithelial cancer is some part of the mucous membrane the mouth and respiratory passages suggest themselves as very obvious channels. Again, the wearing of long skirts sweeping the ground, together with the open and loose arrangement of their nether garments, suggests another obvious channel of entrance in the case of women, who notoriously suffer from cancer of the generative organs. Mr. G. E. Mould of Sheffield describes What to do in a Case of Recent Insanity, and Dr. E. W. Adams of Sheffield contributes an excellent article on the scientific work and the far-reaching influence of Morgagni

Edinburgh Medical Journal.—The original communications in the May number open with an article on Public Health Administration in Fife during a period of ten years, by Dr. T. G. Nasmyth, medical officer of health of the county. Dr. John Macpherson, Commissioner in Lunacy for Scotland, discusses Insanity in Relation to Fertility, his inferences being drawn from a study of the vital statistics of Ireland for a long series of years. He considers that the great increase of insanity in Ireland is due primarily to the depletion of the population by emigration and more immediately to the growing disinclination for marriage and to the diminution of the Irish birth-rate, which is now among the lowest in Europe, with perhaps the single exception of France. Dr. G. A. Gibson, the editor, publishes the second of his lectures on the Nervous Affections of the Heart.

Scottish Medical and Surgical Journal.—The original articles in the May number are on Trophic Changes the Result of Nerve Injury, by Dr. Alexander James; on the Diagnosis and Treatment of Iritis, by Dr. A. Maitland Ramsay; on the Method of eliciting the "Coin-percussion Sound" in Pneumothorax, by Dr. H. G. Langwill; and on Premature Separation of the Normally Situated Placenta, by Mr. J. S. Ross. A special article on the History and Statutes of the Royal Infirmary of Edinburgh as existing in, or shortly before, the year 1778 abounds in entertaining paragraphs. The "matron or governess" of that day evidently occupied a position of authority which would find favour in the eyes of some of the enterprising "lady superintendents" of modern times. The surgeons' clerk had "to open and inspect dead bodies when desired" and "to electrify those patients for whom electricity is ordered." Another rule directed that "the clerks shall not give any list of the patients, with their diseases, to be published in the periodical magazines or other papers as hath sometimes been done without an application made to the managers and their leave obtained."

Mercy and Truth.—In the May number there is an illustrated account of Mr. Cecil Lankester's medical work at Nathia Gali, a hill station at a considerable elevation in the north-west frontier province of India. In 1902 the Government made arrangements by which the duties of civil surgeon here are carried out by the Medical Mission at Peshawar.

Analytical Records

FROM

THE LANCET LABORATORY.

TABLOID HYPODERMIC STRYCHNINE SULPHATE.

(Burroughs, Wellcome, and Co., Snow-hill-buildings, London, E.C.)

Tabloids containing the following amount of strychnine sulphate are now prepared for hypodermic use: $\frac{1}{30}$th grain, $\frac{1}{40}$th grain, $\frac{1}{60}$th grain, $\frac{1}{100}$th grain, and $\frac{1}{120}$th grain. We have carefully assayed the tabloid said to contain $\frac{1}{40}$th grain with the result that we found exactly the quantity of strychnine sulphate stated. These hypodermic tabloids are certainly valuable and especially in cases of emergency.

"VEDA" BREAD AND BISCUITS.

(Veda Food Co., 8, North Bridge, Edinburgh. Agency: Messrs. Bonthron and Co., 50 and 52, Glasshouse-street, Regent street, London, W.)

An important dietetic feature of Veda bread is that its carbohydrates are largely in a soluble state. According to our analysis a third part of the total solid constituents is soluble in cold water while two-thirds are soluble in hot water; accordingly, the bread readily yields to the converting action of diastase or the pancreatic ferment. The taste is somewhat "treacly" owing to a slight charring of the malt sugar present. Veda bread is much more digestible than ordinary white bread. The mineral matter amounted to 1·19 per cent., the moisture to 36·46 per cent., and the proteid to 12 per cent. Biscuits made with the same meal showed a similar high degree of solubility. The mineral matter in this case, however, amounted to 2·47 per cent., which showed an alkalinity equal to 1·34 per cent. of sodium carbonate

NON-NICOTINIC CIGARS.

(Kissling's Non-nicotinic Cigar Agency, 15, Fore-street, London, E.C.)

We have examined several different specimens of these cigars with regard to the quantity of nicotine. We found that the nicotine varied from 0·15 to 0·18 per cent. The amount of nicotine in tobacco is very variable, but even accepting the lowest quantity ever recorded it is evident that a very considerable reduction in the amount of the poisonous alkaloid has been effected in these cigars. We have not had the opportunity of examining these cigars before they were submitted to the eliminating process, but the amount of nicotine in cigar leaf is generally somewhere between 4 and 1 per cent. In spite of this withdrawal of nicotine the cigars are quite satisfactory from the point of view of the smoker. They give a smoke of pleasing aroma, in which no difference can be detected from the smoke produced from a cigar of good quality which has not been treated in the special way indicated. The best specimens, we think, are those described as "Flor Real."

LEMONA.

(Lemona, Limited, 13, Bartlett's-buildings, Holborn-circus, London, E.C.)

According to our examination this toilet preparation would appear to consist simply of pulped lemon fruit. It is a yellow, creamy substance possessing the agreeable and fragrant odour of the lemon. Our analysis gave the following results: moisture, 87·80 per cent.; citric acid, 5·81 per cent.; and mineral matter, 1·13 per cent. The preparation produces a pleasant cooling effect upon the skin. Lemon juice is reputed to be a useful application to an irritable skin and soothing to the face after it has been exposed to the sun or wind. For this purpose this preparation is well suited, and on the whole lemona is a useful, agreeable, and harmless application for the skin.

OLD BRANDY.

(Thomas Peatling and Sons 8 and 9, Old Market, Wisbech.)

Both taste and the results of analysis are in favour of this spirit being a genuine grape brandy. It has the peculiar merits of matured eau-de-vie of Cognac—soft and mellow to the taste and with pleasing aroma. Analysis gave the following results: extractives, 0·70 per cent.; alcohol, by weight 40·30 per cent., by volume 47·67 per cent., equal to proof spirit 83·54 per cent. The following were the results in regard to secondary products given in grammes per hectolitre of absolute alcohol present: volatile acidity reckoned as acetic acid, 100·80; aldehydes, 12·60; furfural, 1·68; ethers, as ethyl acetate, 138·60; and higher alcohols, 138·60. These results are typical of genuine matured grape spirit.

BADEN-BADEN MINERAL WATER.

(Baden-Baden Mineral Springs Co., Terminus Chambers, 6, Holborn Viaduct, London, E.C.)

The chief constituents of this water according to our analysis are chloride of sodium, carbonate of sodium, and magnesium and calcium salts. We could find no appreciable amount of lithium when operating upon half a litre of the water. The water is pleasantly sparkling and has an agreeably soft though somewhat saline taste. It contains 2·743 grammes of salts in solution per litre as follows: sodium chloride, 2·310; sodium carbonate, 0·159; calcium and magnesium carbonates, with sulphate of the former, 0·274. We cannot indorse its claims in regard to containing any important quantity of lithium salts.

MARKING INK.

(George Vickers, Angel court, 172, Strand, London, W.C.)

According to our examination the vehicle of this ink is amylic alcohol of which it smells strongly. We have given the ink practical trials and find that it answers admirably. The ink is indelible, does not spread on the fabric, and gives a good clear black stroke.

BARCO FOOD.

(Moss Rimmington and Co., Portholme and West Riding Mills, Selby.)

There is nothing strikingly novel about this preparation. According to microscopic examination it is a cereal food modified by dry cooking. The starches are therefore broken up and to some extent altered so that its solubility is higher than that of ordinary wheat flour.

HUNTER BALTIMORE WHISKY.

(W. Lanahan and Son, Baltimore; A. A. Baker and Co., 30, Mincing-lane, London, E.C.)

In The Lancet of Jan. 24th, p. 245, we published an analysis of a sample of Baltimore rye whisky which showed a relatively low alcoholic strength. We understand that this sample was meant for exportation. We have since received samples of the same whisky intended for home trade. Analysis gave the following results: extractives, 0·21 per cent. ; alcohol, by weight 40·80 per cent., by volume 48·21 per cent., equal to proof spirit 84·49 per cent. As will be seen the alcoholic strength of the specimen recently analysed is about that of ordinary malt whisky. The spirit possesses the peculiar flavour and smell of rye spirit. It contains a relatively small amount of secondary products and from this point of view may be regarded as very pure.

MALTICO.

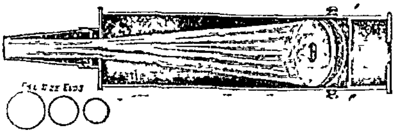
(TAYLOR AND SONS, KINGSTON CROSS, PORTSMOUTH.)

This infants' food is described as being "prepared from the best and purest milk and the extracts of various nutritive malted cereals." According to our analysis it is perfectly free from starch which in the original grain has been converted by the action of diastase chiefly into maltose. Our analysis gave the following results: moisture, 0·90 per cent.; mineral matter, 3·10 per cent. ; milk fat, 8·40 per cent. ; maltose, 67·81 per cent. ; dextrin, 7·79 per cent. ; and proteid, 12 per cent. It will be seen that this food contains all the elements necessary for the infant's dietetic requirements. It would be an advantage, however, if the proportion of fat were increased. Made with milk the preparation gives an excellent infant food rich in all classes of reparative material. No less than 90 per cent. of this food is soluble in water and therefore it is readily digestible.

New Inventions.

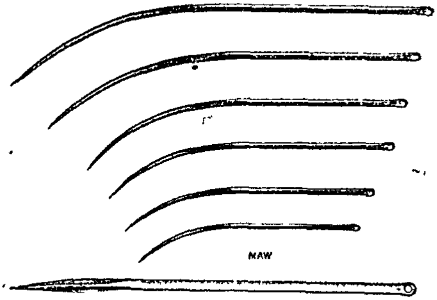
AN IMPROVED OTOSCOPE.

DR. J. B. BALL, physician to the throat and ear department of the West London Hospital, writes: "A magnified image of the drum membrane often reveals changes not otherwise discernible Instruments in which a speculum, a reflector, and a magnifying lens are combined in one piece have long been used for inspection of the ear. Mr. Davidson, of 140, Great Portland-street, has constructed at my suggestion an otoscope of this kind. It is small and very portable. The interior of the otoscope and specula, instead of being bright as in the otoscopes at present most in use, is dead black. This brings out by contrast the image of the parts to be examined with striking clearness. It can be used with good daylight, sunlight, or artificial light It is fitted with three specula of different sizes which can be used separately with the frontal mirror if desired The interior of the specula is first bronzed and then blacked and they may be sterilised by boiling without the blackened surface being affected. The exterior of the instrument is heavily plated so as not to tarnish."



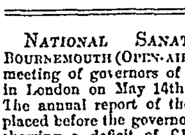
AN IMPROVED SURGICAL NEEDLE.

IN 1900 Messrs Maw and Son of 7, Aldersgate street made to my design a needle specially suited to abdominal surgery. The main features of this needle are three. Firstly, the point, which is triangular or bayonet-shaped, this being, I consider, the best both for penetration and for avoiding the cutting of tissues (and consequent bleeding) which is such a drawback to the Hagedorn point, especially where one is dealing with tissues like the uterine wall Moreover, the point is an easier one to grasp during withdrawal, either with the forceps or with the hand, than that of the latter needle which invariably either turns on edge or cuts the fingers. The second feature is the eye, which is similar to the round Hagedorn eye and like that pattern is threaded easily. The third and last peculiarity is the haft, which is flattened at right angles to the plane of the curve in a manner similar to that which obtains in the so called "reversed" Hagedorn needle. The advantage of this flattened haft is the excellent hold that can be got upon the needle with an ordinary Spencer Wells pressure forceps, thus dispensing with various forms of needle holders, all more or less clumsy and irritating, and simplifying the surgeon's outfit. The needles are made in three different curves and in a number of sizes from very large and strong weapons suitable for the various forms of perineorrhaphy down to the smallest sizes required for intra-peritoneal operations. The results obtained from an extended trial of this type of needle both by myself and others lead me to deem it the most convenient needle for abdominal surgery.



Devonshire street, W. W. F. VICTOR BONNEY, M.D. Lond.

AN OPHTHALMIC DRESSING-TRAY.



THE accompanying illustration represents a tray for use in irrigation of the eye and has been suggested by Nurse Manchester of Guy's Hospital who has previously designed a useful dressing tray for colotomy cases. The present tray is so shaped as to fit against the face and when used with the patient in the recumbent position it rests on the pillow and adapts itself closely to the face. It certainly answers the purpose for which it is intended and in addition will be found useful when syringing the ear. The tray is made by Messrs. Down Bros., Limited, 21, St. Thomas's-street, London, S.E.

NATIONAL SANATORIUM FOR CONSUMPTION, BOURNEMOUTH (OPEN-AIR TREATMENT).—The annual general meeting of governors of this charitable institution was held in London on May 14th at the Westminster Palace Hotel. The annual report of the committee for the year 1902 was placed before the governors, with the statement of accounts showing a deficit of £109, which, added to the existing debt of £431, amounts to a total deficiency of £540. The secretary, however, informed the committee that so far there has been some improvement in the receipts this year. The report stated that a special appeal is being made in order to put the institution in a better financial position, pointing out that the benefits of the National Sanatorium are not limited to the patients who enter it, but extend to the public generally, for every case in which the disease of consumption is arrested removes a source of infection to others. Moreover, every patient is taught the laws of hygiene and the means of preventing the spread of the disease to others and the re-infection of themselves. Upon the national character of its work the committee relies for a generous response to its appeal. The report further states that during the year His Majesty the King was graciously pleased to send a donation of £100.

THE LANCET.

LONDON: SATURDAY, MAY 23, 1903.

The Metropolitan Hospital Sunday Fund.

The meeting of the Council of the Metropolitan Hospital Sunday Fund which was held under the presidency of the Lord Mayor on May 12th, and a report of which will be found in our columns last week, was particularly notable owing to two announcements which were officially made thereat. The one was that the Hospital Sunday Fund collection would be made at St Paul's Cathedral on June 7th, being the date upon which their Majesties the King and Queen would be present to worship and to benefit the London hospitals. The other was that Mr. George Herring repeated his offer of giving £10,000 to the Fund, or one fourth of the whole amount collected, provided that this did not exceed £100,000. The Lord Mayor in his speech pointed out that the whole deficiency of the London hospitals amounted to £250,000 per annum. If, he said, King Edward's Hospital Fund could raise £100,000 per annum, the Metropolitan Hospital Sunday Fund £100,000 per annum, and the Hospital Saturday Fund £50,000 per annum, then no assistance from the rates would be required. He was glad to say that nearly every bank in the City had sent him a donation for the London Hospital and he further adjured the banks and the limited liability companies to contribute to one of the three funds above mentioned. This is a matter upon which not sufficient stress has been laid. When the large businesses were in the hands of personal proprietors contributions were made to charities which are no longer made by the companies which have replaced those proprietors. The boards of directors cannot have personal claims made upon them as the heads of private businesses can, while directors have responsibilities towards shareholders which prevent them from giving way to private feelings of generosity. We hope that directors of limited liability companies in London will recognise the justice of the claim upon the funds which has been urged upon them this year by the Lord Mayor.

Last year the total of the sum received was very nearly £63,000, a larger amount than had ever before been collected. This was a source of credit to everyone concerned, for although there were many circumstances which went to make men and women subscribe—such as its being the year of the coronation of the King and the year in which peace was declared—yet the country had just passed through a costly and lengthy war with the consequence that trade was depressed and taxation was high. This year has seen the lowering of taxation and so we may well hope that the total collected will reach the sum of £100,000, the sum which we have always had before our eyes as the ideal to which the Fund should annually attain. One thing must be remembered, nearly all other charitable collections are unfortunately limited by religious differences. If it be true that

"All equal are within the Church's gate"

still more true is it that sickness and death level all. To the Metropolitan Hospital Sunday Fund all can and do contribute. The Christian, the Jew, and the Mussulman, to say nothing of the members of the many other religions or no religions within our great Empire, all can give of their wealth or of their poverty and like Abou ben Adhem each one desires to be simply written "as one who loves his fellow-men." The influence of a hospital is the true communiser of charity and the surgeon or the physician who on one day gives his skill, under God, to heal a monarch on the next day gives the same skill to heal the poorest in the land. Here are no politics and no bitterness, therefore everyone from the highest to the lowest should contribute. Doubts have been raised as to the wisdom of making the collection upon two different Sundays. We think that on the whole the step is well advised. "Week-ends" are now having a serious effect upon the attendance in our metropolitan churches. The bicycle, the motor-car, the links, and the river draw away hundreds whose excuse is that they are obliged to obtain fresh air and exercise upon their only free day in the week. The collection of Sunday, June 7th, will remind those who do not go to church or chapel that if they do not attend any place of worship on the following Sunday they can and should at least send a subscription to be added to the subscriptions of those who do attend. Let those who are able to seek the country and the free air on a Sunday remember that the hospitals exist for those whose need for health is as great as, or even greater than, their own. Let them remember that if they fall ill they will be tended and possibly restored to health by the skill of one who without a hospital would scarcely have attained that skill. The benefits of the Hospital Sunday Fund are impartially bestowed; a gift from it is a guarantee of sound finance and of good management. Therefore, anyone who gives will feel not only the pleasure of giving but may rest assured that his gift will be laid out in the best possible manner.

In connexion with Mr. George Herring's great and repeated generosity we should like to see urged upon the racing men of the community the claims of the great London hospitals, so that something like a movement might be inaugurated among them to devote a small percentage of their winnings to the succouring of the necessitous poor. The late Baron Hirsch's dedication of a great proportion of his winnings to charity will be remembered, but every devotee of the turf is not a millionaire. Still, every winner can spare something. The idea is not a new one. More than 40 years ago Mr. Joseph Bond, a gentleman well known in connexion with racing, made an offer to the stewards of the Jockey Club which, if it had not been rejected, might have initiated a movement of inestimable value to the London hospitals. Mr. Bond repeated his offer in a letter addressed to the Editor and published in The Lancet of July 5th, 1862, in these words: "My present most earnest appeal (in anticipation of any general measure to be taken by the Jockey Club) is made to the fortunate winners of the Derby and Oaks—viz., that if *they* will kindly consent *this year* to an allocation of 10 per cent. of their winnings" for the benefit of the London hospitals, "I will with pleasure add a contribution of 1000 guineas; but should such percentage be deemed excessive I shall be happy to give an amount equal to *five* per cent. upon their stakes respectively." It will be seen from this that the idea which actuated Mr. BOND was that by getting the owners of two winners of large stakes in a particular year to tax their gains for the benefit of the hospitals he could bring about a general deduction to be made by the assistance of the Jockey Club from all such winnings in the future, and no doubt from all or from a large portion of the stakes of each year. These stakes Mr. BOND put at £200,000 per annum—an amount which, of course, has long ago been largely exceeded. "My constant endeavour," Mr. BOND wrote, "will be to place the turf as an institution in closer affinity with the sick poor of our needy and unendowed London hospitals." In the years that have passed since Mr. BOND wrote these words the hospitals have grown no less needy, no less unendowed: their needs have increased with the population of the metropolis and their endowments have not kept pace with the demands upon their resources. Mr. BOND'S great idea has not borne fruit in any organised taxation of turf profits but a worthy successor to him has arisen in Mr. HERRING, whose princely generosity of last year is to be repeated in 1903. When in 1862 Mr. BOND found that the winning owners to whom he had appealed had not responded to his challenge, he nevertheless carried out his part of the undertaking, and his gift of £1000 was divided, the greater part being given, largely through the medium of THE LANCET, to seven London hospitals and the remainder devoted to the provision of a drinking fountain in the parish of St. Clement's Danes. Mr. BOND also presented to the hospitals some valuable works of art which were placed either in the convalescent wards or board-rooms, where they will be found at the present time—fitting memorials of his generosity and of his well-intentioned efforts. From the hundreds of thousands of pounds which change hands every year upon the turf we would claim a percentage for the suffering poor in the London hospitals and would welcome an attempt at an organised movement on these lines this year.

◆

Personal Performance of Duties by the Workhouse Medical Officer.

A MEDICAL man commencing practice may be inclined to avail himself of an opportunity of becoming medical officer at the union workhouse. He sees in the appointment the source of a small addition to his income—an addition somewhat attractive, not by the pleasantness of the work to be performed for it, but by reason of the certainty and punctuality in the payment. Probably it will occur to him that if he himself should fail to step into the vacant post some other person will inevitably be installed and that the other person in consequence of the help afforded by the appointment may become a permanent competitor with him for the practice of a district too small to supply the needs of more than one practitioner. Rarely until he has entered upon his duties does the newly elected workhouse medical officer realise the exacting nature of the conditions which will affect him during his tenure of the position. Nor will the contract which he is required to sign make clear to him all the irksome limitations and responsibilities to which he is expected to submit. A search through the General Consolidated Order of 1847 and the notes upon it will, however, reveal the terms of his engagement and enable him briefly to set forth some of the more important of those terms in the form of the paragraphs given below:—

(*a*) Every officer of the union shall perform his duties in person and shall not intrust the same to a deputy except with the special permission of the Commissioners (now the Local Government Board) on the application of the guardians.

(*b*) The medical officer shall be bound to visit and attend personally, as far as may be practicable, the poor persons intrusted to his care and shall be responsible for the attendance upon them.

(*c*) The medical officer cannot expressly delegate to his assistant in his general practice the duties of his office, however well qualified, legally or otherwise, such assistant may be.

(*d*) Though an assistant may visit a patient or aid his principal in the performance of his duties no diminution or subdivision of the duty of personal attendance and personal responsibility on the part of the medical officer will be recognised on that account.

(*e*) The medical officer must immediately after his appointment name to the guardians some legally qualified medical practitioner to whom application for attendance may be made in the case of his absence and the medical officer will be responsible for the skill and diligence of the person named by him. The name and address of every practitioner so named must be forwarded by the clerk to the guardians to each relieving officer and to the overseer of every parish in the district of such medical officer. The guardians have the power to object to the appointment of the practitioner so named if they should not approve of him.

(*f*) The visit or attendance made or given to any pauper by any person employed by the medical officer must be shown in the book prescribed under the General Consolidated Order of 1847. Medical men not being medical officers of the union are not entitled to any fees under the same order for operations performed upon paupers or services rendered except by the will of the guardians.

(*g*) The medical officer must not only attend at the workhouse at the periods fixed by the guardians but also whenever he is sent for by either the master or the matron. He must record every attendance in a book provided and give a return to the guardians at each meeting of the particulars of the attendance. It is the duty of the master to cause every pauper upon admission to be examined by the medical officer; to send for the medical officer when any pauper is taken ill; and to take care that all sick paupers are duly visited by the medical officer.

It may be gathered from the above statements that the task of the workhouse medical officer is no light one; that the mere labour of going to and from the workhouse, apart from the work there to be performed, may be a matter of great moment; that the medical officer's comfort depends to a large extent upon the temperament of the workhouse master who may see serious symptoms in every simple ache of an inmate; and that the rigid requirements of the Local Government Board as to personal attendance are particularly burdensome to a medical man who has a private practice of even moderate size. The question has been put to us—Are these rigid rules for personal service absolutely necessary? The answer must be—They were necessary at the period of their institution but they are so no longer; neither is it possible for them now to be observed in the large workhouses. At the date of the issue of the General Consolidated Order a vast amount of medical work in the practices of the country was performed by unqualified assistants and by pupils or apprentices. It was fitting, therefore, that the Poor-law Commissioners should impose conditions upon all holders of parish medical appointments and they did so effectually. Their object was to prevent the sick and infirm inmates of the workhouses being left to the care of persons only partially educated in their professional duties. The result was good, but times have changed and there is now justification for a reconsideration of the circumstances. The pupils and the unqualified assistants have had their day. Few of them can at this period be found. The assistants of medical practitioners are not only legally qualified to practise their profession but their training at the hospitals has been, both in duration and in the number of subjects taught, far beyond that given to the principals of 1847. We therefore arrive at the conclusion that there is no longer any necessity for the workhouse medical officer to be debarred from using his duly qualified assistant as a substitute, within certain limits; always providing that the qualified assistant has been named to the guardians and approved by them.

There is, however, another aspect. Workhouses have grown immensely in size since the regulations for their administration were constructed. Many can now be found each containing over 1000 inmates and many have in their sick wards more than 500 patients. One that is well known to us is not by any means the largest but it has over 1700 beds without the infirmary, which contains nearly 300 more. For this vast population there is but one recognised medical officer. Obviously it is impossible that he can give personal service in every case of sickness. One minute a day for each of 600 patients would mean ten hours' work. The difficulty is met by the appointment of several assistants and by the division of the medical duties. In another workhouse infirmary there are two non-resident medical officers and two resident assistants, but which is the responsible official it is beyond our power to decide. We mention these facts in order to show that the regulations of the General Consolidated Order of 1847 are not observed in all Poor-law institutions, that owing to the numbers of the patients to be attended they cannot possibly be observed in every workhouse by one medical officer, and that a revision of the regulations and an adaptation of them to modern conditions are much to be desired.

◆

The University of London and Dental Surgery.

As the Faculty of Medicine of the University of London has under consideration the institution of degrees in dental surgery, it may be opportune to consider briefly the various phases of this important question, and the more so as there is a marked divergence of opinion among those who have considered this matter in its bearings upon dental education. There is a section which considers that the right course to pursue for the advancement of dental surgery is to raise the standard of the training all round, in fact, to bring the general curriculum up to the standard required of students of medicine as a whole. On the other hand, a considerable, if not so numerous, body of persons, having a good right to form an opinion, hold that the advance should be made by the institution of higher dental degrees, the curriculum being rendered more stringent mainly by requiring from the student a wider and deeper knowledge of the special subjects of dental surgery. These two parties are both represented on the board of studies of dental surgery of the University of London and they have embodied their views in two reports which are now under the consideration of the Faculty of Medicine. The majority report, we believe, considers that if the University deems it advisable to institute a degree in dental surgery then it should only be granted supplemental to a medical degree. The minority report advises the institution of a separate degree in dental surgery, the requirements in general subjects being in advance of those at present demanded by the different licensing bodies.

Under the Dentists Act the only registrable diploma in the United Kingdom is a licence in dental surgery and this is at present granted by the Royal Colleges of Surgeons of England, of Edinburgh, and in Ireland, and the Faculty of Physicians and Surgeons of Glasgow. The framers of the Dentists Act were strongly of opinion that only one diploma should be instituted for practitioners in dentistry so that the multiplicity of qualifications, which has imported many difficulties into the practice of medicine in this country, should be avoided. Their action was sound and all educational bodies should agree with it and should keep clearly in view that the object of degrees and diplomas is mainly to guide the public so that the public may know when it is dealing with a qualified man. The multiplicity of qualifications is bewildering to the public and serves no good purpose It leads it to attempt to discriminate between one qualified man and another qualified man, while protection is really needed against the charlatan and quack who frequently place after their names meaningless letters simulating regular qualifications. The University of London in establishing examinations in dental surgery will either grant a licence similar to that of the various colleges or it will establish a degree which can be registered as additional to the licence in dental surgery obtained through one of the medical corporations. If the desire of those urging upon the University the establishment of a dental degree is that the examination should be considered a qualifying one in dental surgery similar to that of other colleges, then there is no reason why the University should not grant a licence in dental surgery; but if the desire is that the degree should be regarded as a higher qualification than the licence in dental surgery then we are strongly of opinion that it should only be conferred as supplemental to a medical degree. Dentistry is to be regarded as an integral part of medicine, a view held, we suppose, by the advocates of higher dental diplomas; and dentistry can only obtain and retain that position by examining its students in a similar way to that in which other members of the medical profession are examined.

The weakness of the present qualifying examinations in dentistry lies in the low standard of knowledge required on general subjects and any step towards higher qualification can only rationally be made by requiring a better foundation of knowledge. The scheme suggested by the majority of the board of studies is that a degree in dental surgery (even if it is advisable to establish one) should be granted only to those possessing the M.B. and B.S. degrees of the University. The minority suggests that the student for the degree should pass the first examination for the degree of M.B. and that the examination in surgery and pathology should be similar to that for the degree of B S. Medicine and therapeutics are, it will be seen, to be ignored not only in the curriculum required but also in the examination. The latter scheme seems to us to be retrograde, for day by day it becomes clearer that a thorough knowledge of the surgical branch cannot be acquired without a comprehension of the principles and practice of medicine as a whole. If the practice of surgery were confined to operations then perhaps the position assumed by the constructors of the minority scheme for the granting of dental degrees in the University of London might be intelligible, but surgery is not a higher grade of cabinet-making. Surgery entails for its scientific practice a thorough knowledge of the principles underlying medicine as a whole. Dental surgery may be regarded from exactly the same standpoint. In some quarters it has been, and still is, the tendency to estimate the practice of dentistry as something requiring simply manipulative dexterity, but this view has arisen partly from a want of knowledge of the processes underlying dental disease and not a little from that narrowed vision which the training of the dental surgeon produces and which can only be made broader by raising the standard of general and scientific education. With the increased number of medical men specially qualified as dental surgeons a marked advance in dental pathology has taken place and the inter-dependence of dental lesions, more especially of the gums and periodontal membrane, and general systemic conditions has been shown. The dental surgeon in his practice is constantly dealing with cases which require for their rational treatment a knowledge of medicine, a fact which the authors of the minority report do not appreciate, in our opinion, in its right significance. They would not, we are sure, consider that such well-defined branches of medical practice as, say, ophthalmic surgery or gynæcology, should be practised by men with only a scant knowledge of general medicine and surgery. To our thinking, dental surgery should rank with the other special branches; at any rate, all who practise dental surgery should be found wishing this, for only in this way can the scientific status of dentistry be maintained.

Annotations.

"Ne quid nimis."

THE ROYAL MILITARY TOURNAMENT.

FROM a practical point of view one of the most interesting items in the programme of the Royal Military Tournament now being held at the Agricultural Hall, Islington, is the display by the recruits from the Marine depôt at Deal who have been in the service for six months only and whose average age is 18 years. These lads have had but 45 days' gymnastic training, yet their muscular development, agility, and smartness in response to the word of command are wonderful considering the brief period of instruction. The exercises which they go through bring into play all the important muscles of the body and educate at the same time the intellectual faculties. In previous years at the Tournament similar exercises have been practised by non-commissioned officers under training at the headquarters gymnasium, Aldershot, who if we mistake not underwent a six months' course and not a 45 days' course. Undoubtedly the non-commissioned officers from Aldershot showed remarkable muscular power combined with intellectual activity both while acting individually and collectively. So do the Marine recruits, but it is distinctly noticeable that some of them are working at the highest possible strain. It speaks well both for officers and for men that such remarkable results should have been accomplished in so short a period as 45 days, but there must be always some risk in a too strenuous and hasty endeavour to build up muscle. It remains to be seen what the effect will be when, after completing their course, the men relax their training, for it must be remembered that over-taxation of the vascular system may produce untoward results at a subsequent time. A curtailment of the period of training may, therefore, in the end be a means of loss instead of gain to the service. Another noteworthy example of strength and ability is the display by the Royal Marine Artillery. The general idea of this display is to show how a gun with its mountings landed from a man-of-war can be transported and mounted in an extemporised manner on shore. The gun, mounting, and stores, together with the wagon on which they are placed, weigh six tons and are drawn into the arena by 38 men. The slinging and unslinging of the gun on the extemporised gin require some skill and precision in placing the gun centrally. When the men begin this kind of training the weights with which they have to deal tax their strength to the utmost. At the Tournament, however, the gun is manipulated with as much ease as if it were a toy. Altogether this is a truly remarkable performance. In this connexion it would not be fair to leave unnoticed the display by seamen of His Majesty's ship *Excellent* with 12-pounder guns. The way in which these guns are manœuvred, mounted and dismounted, and lifted with ease over an obstacle representing a wall must be seen to be appreciated. These three items in the programme alone form an object-lesson which it would be well for everyone to see.

INSURANCE AGAINST APPENDICITIS.

THE sudden increase in the popular knowledge of appendicitis has given rise to the idea that the malady occurs more frequently than is really the case, with the result that it is dreaded more than it need be. So it has even happened that it has been thought advisable to insure against the loss of time and of money entailed by an attack. The Royal Exchange Assurance Company is willing to issue policies of insurance at the rate of 5*s*. per annum for every £100 and a policy may be effected up to £500. By such a policy the holder is guaranteed all the medical, surgical, and nursing expenses, up to the amount insured, incurred by an attack of appendicitis. The company points out that this premium may be largely increased in the near future, for it is obvious that at present the "risk" of such a policy can be only very indefinitely estimated. The only data supplied by the leaflet which we have seen are that during 1900 15,000 operations for appendicitis were performed in the United Kingdom and that the mortality of these operations was 10 per cent. We are not aware whence these statistics have been obtained and, in fact, we cannot see how it is possible to discover the number of operations because the vast majority are never recorded. Be this, however, as it may, it must be borne in mind that many cases diagnosed as appendicitis recover without operation and therefore the total number of cases should be much greater. In the proposal for insurance there is one important question to be answered. It is this: Have you or has any member of your family ever suffered from appendicitis or from any of the symptoms pertaining to it? This is a very wide question, for apparently a negative answer would mean that neither the would-be insurer nor any member of his family had ever had a pain in the right iliac fossa. Another difficulty is that it is not clear what the word "family" includes. It is possible that this question in-

inscribed only to obtain statistical information as to the family liability to appendicitis, for at present it cannot be laid down that the disease is specially prone to attack certain families. In the "declaration" also the insurer has to state that he has no reason to believe that he is specially liable to the disease. There is one important condition attached to these policies: the liability of the company does not commence until one month after the proposal has been accepted and the premium has been paid, so that it will not be possible for anyone who experiences symptoms which he thinks may be due to appendicitis to rush off and to insure. The utility of the scheme depends entirely on the liability there is to an attack of appendicitis. Should the disease arise the loss of money incurred by medical, surgical, and nursing expenses would certainly be very troublesome to many and anyone attacked would be very glad to have insured against this sudden expense by the payment of such a small premium and if anyone feels inclined to insure there cannot be any harm in doing so. From the amount of the premium we see that the company estimates the probability that any individual will be attacked by appendicitis in any one year as at most less than 1 in 400 and we should feel inclined to think that the risk is very much less than this, but no statistics exist to show the percentage of attacks in the general population though they may be obtainable for such bodies of men as the army and the navy. As many cases, in this country at least, are not submitted to operation disputes might easily arise as to the accuracy of the diagnosis. Moreover, it has not rarely happened that appendicitis has been diagnosed, the abdomen has been opened, and some other lesion has been found. If the patient had been insured we can imagine his disappointment when he found that the fees and other expenses were payable out of his own pocket. We would not in the least dissuade anyone against insuring, but we must confess that in our opinion a wider policy to include any similar severe illness would prove much more useful in practice. At present it is possible to insure against sickness and accident, but the sum paid is so much per week and does not necessarily cover the expenses incurred.

NOTIFICATION FEES.

NOTWITHSTANDING the fact that the Notification Act has now been in operation for many years the subject of the fees payable under its provisions seems to be a never-ceasing topic for discussion and dispute. This is, we expect, partly due to the fact that a copy of the Act itself is possessed by few medical men and partly to the absurd fee of 1*s*. which is paid to those who notify cases of notifiable diseases in their capacity as officers of public institutions or bodies. We can quite understand that district medical officers under the Poor-law and others who are not quite familiar with the statutes are unwilling to believe that the legislature has provided no further fee than 1*s*. for the trouble of notifying the cases of infectious disease with which such officers are brought into contact during the performance of their official duties. We have recently had a case brought to our notice of a district medical officer who is content with the customary 1*s*. for cases concerning which he has received a relieving officer's order but who claims 2*s*. 6*d*. in respect of subsequent cases occurring in the same house but as to which no order has been given. We are afraid, however, that, assuming that the cases were treated by the district medical officer in his official capacity, the smaller fee is the only one that can be legally paid. The words of the Infectious Disease (Notification) Act, 1889, which govern the situation, are: "and of one shilling if the case occurs in his practice as medical officer of any public body or institution." Unless, therefore, the cases to which reference has been made were attended by the district medical officer in his capacity of a private practitioner he is not entitled to the larger fee of 2*s*. 6*d*. It would seem improbable, seeing that an order had been procured for one member of the family, that any other member thereof could be regarded as employing a medical man as a private practitioner, and it would seem more probable that there has been some omission on the part of the relieving officer or the district medical officer, in the one case in supplying an order or in the other of notifying the fact of attendance without an order. So far as we are in possession of the facts we do not think that the case to which we refer is one in which a fee of 2*s*. 6*d*. could be reasonably claimed.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE Council opened its summer session on Thursday, May 21st, at 2 P.M., Sir William Turner, K.C.B., the President, being in the chair. The session this year is being held somewhat earlier than usual in order that Whitsun-week may be avoided. After hearing the President's address the Council proceeded to the consideration of various matters of medical education. Our usual report of the proceedings will be commenced in our next issue.

THE PHARMACEUTICAL SOCIETY.

THE annual dinner of the members of the Pharmaceutical Society of Great Britain and their friends was held under the chairmanship of the President, Mr. G. T. W. Newsholme, in the Whitehall Rooms of the Hôtel Métropole, London, on May 19th. After the usual loyal toasts had been duly honoured Mr. Newsholme from the chair proposed the toast of "The Houses of Parliament," which was replied to by Mr. J. F. Remnant, M P., who, referring to the new Pharmacy Bill, said that he had heard some criticism in the House in regard to that clause which says that a director of a company must be a qualified druggist before he can deal with the ordinary business of a druggist. Concerning that matter there was an opinion given in the House of Lords that the Act could not apply to directors of limited liability companies. This toast was also acknowledged by Mr. E. Marshall Hall, M.P., who declared that the new Pharmacy Bill could not pass into law in anything like its present form and he advised the society to accept half a loaf as better than nothing at all. He suggested that the Pharmaceutical Society should obtain powers over its members in the same manner as the General Medical Council has over medical men. If it could bring the power, influence, and prestige of the society thus to bear on its members then it would have a remedy against the evils which it was anxious to eradicate. Mr. Marshall Hall bluntly told his audience that a large portion of the business of a druggist as now carried on could be intrusted to unqualified assistants and even to shop lads. So long as the public made no discrimination between a qualified druggist and a salesman of sundries so long would it be difficult for Parliament to deal with the evil. But the Pharmaceutical Society armed with the powers which he had suggested could undertake the matter. In regard to the companies trading as druggists the department particularly concerned with the business of the druggist should be managed by a properly qualified druggist. The toast of "The Medical Profession" was proposed by the chairman and responded to by Sir William S. Church who drew attention to the embarrassing multiplicity of the compounds turned out for the use of medical men by the synthetical chemist. If physicians needed to be careful in the use of drugs the public ought to be careful in the use of the so-called chemical foods, though if one half of the advertisements about these foods could be believed not only would they ward off disease but they would even overcome death itself. The chairman then proposed "The Pharmaceutical Society of Ireland" which was acknowledged by Mr. G. D. Beggs. He was followed by Sir A. W. Rücker, principal of the University of London who, in proposing "The Pharmaceutical Society," gave in detail the reasons for hoping to effect some connexion between the new University of London and the society. The chairman suitably acknowledged the toast and then proposed "Local Pharmaceutical Associations" which was acknowledged by Mr. W. Giles of the Aberdeen Pharmaceutical Association. M. E. Léger of the Pharmaceutical Society of Paris responded to the toast of "Our Guests," which was proposed by the chairman, after which the proceedings terminated.

THE PATHOLOGY OF DWARFISM.

THE pathology of dwarfism like that of gigantism has for long remained an obscure matter and it is only recently that light has been thrown upon the morbid processes underlying both these conditions of abnormal bodily development. In THE LANCET of March 14th, p. 747, an account was given of the pathology of gigantism and it was shown that certain cases of extraordinary growth in length of the bones and limbs were due to a morbid process allied to the condition known as acromegaly. In the *American Journal of the Medical Sciences* for May Dr. Ludwig Hektoen of Chicago contributes an interesting post-mortem study of a dwarf, which is placed on record as affording further insight into the nature of the pathology of certain obscure anomalies of osseous development allied to cretinism and rickets which result in stunted or dwarfish development. In this case, as in cases of gigantism studied post mortem, certain changes were found in the thyroid and pituitary bodies the significance of which will be alluded to below. The patient was a man, aged 45 years, a short-limbed dwarf, of fair average intelligence. He could not walk very well and earned a living by selling lead-pencils and chewing-gum. He generally used a roller-chair for locomotion. He was given to alcoholic excess and died from a ruptured gall-bladder. The post-mortem examination revealed the following interesting conditions. The long bones of the upper and lower limbs were excessively curved and marked by nodular enlargements, especially at the articular ends. The legs were notably short, the patient being an example of a micromelic or short-limbed dwarf. The spinal column was of average length but there was a marked degree of kyphosis, the whole dorso-lumbar and lumbo-sacral region being strongly curved with the concavity forwards. The viscera did not show signs of organic disease with the exception of the thyroid body which was atrophied, fibroid, and weighed only nine grammes. The aorta was small and measured nine millimetres in diameter. The bones were the chief objects of interest. Sections of the various long bones showed an exceedingly spongy structure (osteoporosis). The spine and pelvis as well as the limbs were unusually bent or misshapen. The cranial vault was relatively large but its structure was most anomalous as it consisted of 172 Wormian bones. The base of the skull showed no evidence of premature synostoses of the sutures. The pituitary body and the sella turcica were much enlarged. In discussing the nature of the morbid process which led to this remarkable hypoplasia and defective development of the skeleton Dr. Hektoen passes in review the four possible etiological factors—rickets, cretinism, osteogenesis imperfecta, and chondrodystrophia fœtalis. The condition of the cranium both as regards its vault and base suggests strongly the presence of osteogenesis imperfecta as described and illustrated in the memoirs of Stilling[1] and Harbitz.[2] Most cases of osteogenesis imperfecta hitherto recorded have, however, terminated fatally in infancy, the present case being a rare instance of a person afflicted with this disease surviving to adult life. The patient was not a cretin, adds Dr. Hektoen, for he had not the physiognomy or the bodily development of a cretin, while his intelligence was of the average grade and he was free from signs of myxœdema. The evil effects of fibroid atrophy of the thyroid gland—a process which ordinarily would give rise to myxœdema or which, if it occurred early, would produce cretinism—were in this case compensated or wholly alleviated by a hypertrophy of the pituitary body the weight of which was found to be considerably above the normal. The histological structure of the pituitary body was, moreover, normal in this case. The patient's ribs were beaded and excessively curved, but, says Dr. Hektoen, ordinary rickets could be excluded in the present case owing to the porosity of the bones, whereas in rickets an increased density of the bones is met with. The lesion was more probably of the nature of so-called "fœtal rickets" or chondrodystrophia fœtalis—"a disease known to have existed even in ancient times, since statues of the Egyptian god Phtah and other deities are good representations of the external appearances produced by this disease," as has been shown by Harbitz (in his memoir referred to above) and by Charcot and Richer in their classical work, "Des Difformes et les Maladies dans l'Art," Paris, 1889. The lesions of the thyroid body and the compensatory hypertrophy of the pituitary body in the present case are apparently conditions giving rise to disturbances in the development of the osseous system—disturbances common alike to gigantism, acromegaly, and dwarfism. The proximate cause of the pathology of dwarfism is thus brought into light and shown to be a nutritive disturbance associated with changes in the thyroid and pituitary bodies, but the ultimate cause of the osteogenesis imperfecta still remains, concludes Dr. Hektoen, a problem for future solution.

TENT LIFE FOR THE DEMENTED AND UNCLEANLY.

THE experiment of treating the tuberculous insane in tents, concerning which subject a leading article was published in THE LANCET of May 2nd, p. 1249, was initiated two and a half years ago by Dr. A. E. Macdonald, medical superintendent of the Manhattan State Hospital East, New York. The scheme proved such a success that it was decided to open another camp for filthy and demented patients. Accordingly in July, 1901, 20 patients of that class were selected for undergoing the system of tent life. At the last annual meeting of the American Medico-Psychological Association held at Quebec last year, a reprint of the proceedings of which now lies before us, Dr. Arthur B. Wright of the Manhattan State Hospital for the Insane gave an account of the working of this scheme. Most of the patients were very stupid and demented, taking little or no interest in their surroundings or in their own welfare. Of the 20 patients it was noticed that 19 showed physical improvement and increase of body-weight after three weeks of residence in the tents. The remaining patient continued unchanged a little longer, but after six weeks he began to manifest decided improvement. All the patients improved both physically and mentally and several of them whose habits had been previously wet and dirty began to attend regularly to the calls of nature and to develop more cleanly habits. Two general paralytics exhibited marked improvement. Both at first were practically bedridden but at the end of three months were among the most active. The situation of the camp being in a most pleasant spot on the east bank of the island the steamers and excursion boats which were continually passing were watched by the patients, while the music on board the vessels was listened to with interest. All the patients showed increased appetite, greater interest was shown in papers, magazines, and games, while more cheerfulness and mental brightness seemed to prevail. During warm and pleasant weather the flaps of the tents were rolled up so that a free circulation of air was established, and the few patients who remained in bed were practically out-of-doors. The experiment of tent life for this class of the insane was, adds Dr. Wright, an entire success. Several of the patients have been closely observed since the breaking up of the camp, and it was noted that some of them tended to relapse into their former habits. It is intended, says Dr. Wright, to open another camp during the summer of 1903, for the same class of patients as well as a camp for convalescent patients.

CYCLING AND MOTOR-CARS.

ALTHOUGH cycling is still a popular pastime, yet there is distinct evidence, we think, that it is not so universally or so vigorously pursued as it used to be a year or so ago. Possibly this is due to the counter attractions of golf and motor riding. We rather incline to the view that the cyclist is being gradually driven from the road by the motor-car which all must agree has not made the road a pleasanter highway. It is a common remark that cyclists take more frequently to the by-roads than formerly because the high-roads have been almost monopolised by the motor-car. The noise and dust and pace of the motor-car have taken the poetry completely out of a ride on the high-road. The risks of cycling have been enormously increased and already a crop of accidents to cyclists has been reported having their orgin in fast-driven motor cars. The dust created is not only most unpleasant but also very unhealthy for on any favourite high-road out of London the condition created by the motor-cars is one of chronic dust like a fog. All this doubtless the cyclist can avoid by taking to the by-roads, but when on a tour these roads are often not direct, while their surfaces may not be good and there are no sign-posts or caution boards by the wayside to guide him. At night time the danger to the cyclist from motor-cars is considerably increased. Indeed, to many cyclists the motor car is a source of terror on the road, the timid dismount as soon as they hear its rattle behind them and others, realising what awkward consequences might ensue from a false turn of the steering gear, give the motor-car the widest berth possible. Again, it is to be feared that some few motor drivers, knowing the terror which they inspire and that they are masters of the situation, are deliberately discourteous and allow the smallest margin possible for a cyclist to pass. Is it then a matter for wonder that the healthy and enjoyable pursuit of cycling should be somewhat on the decline? But it is a pity that it is so and we can only hope that impending legislation with regard to the regulation of motor-cars may not ignore the claims of the cyclists to consideration.

THE LYMPHATICS OF THE URETERS.

DIFFERENCES of opinion exist in regard to the distribution of the lymphatics in the walls of the ureters, Krause, for example, stating that the lymphatics form a superficial wide-meshed plexus of vessels in the mucous membrane and a well-developed plexus in the submucosa. The vasa efferentia or larger abducent ducts are situated in the tunica adventitia. Sappey, on the other hand, remarks that in the horse the lymphatics of the ureters arise exclusively in the muscular tunic. If the internal or mucous surface be pricked no vessels appear, but as soon as the point of a syringe charged with mercury penetrates the superficial layer the mercury enters a system of capillaries which forms a very distinct network extending with irregular meshes throughout the whole length of the duct. The subject has again been studied by Dr. K. Sakata, in the Anatomical Institute of Breslau, and his conclusions are that no plexus of lymphatic vessels can be demonstrated by Gerola's method of injection in the mucous membrane or in the submucous tissue of the ureter. Such a plexus is, however, to be found in the muscular tunic and in the adventitia, where the vessels are larger and run parallel to the blood-vessels. The vasa efferentia are most conspicuous in the middle portion of the ureter and pass to the lumbar glands which lie close to the aorta and vena cava inferior and to the mesial side of the common iliac artery. The lymphatics of the lower segment of the ureter terminate either in the hypogastric glands or anastomose with the lymphatics of the bladder. The lymphatics of the upper segment only occasionally end in the glands that lie at some distance at the side of the aorta; in other instances they join the lymphatics of the kidney. The lymphatic vessels which establish a connexion between those of the bladder and those of the kidney do not take a direct course between these organs but either form afferent vessels running to glands or join the lymphatics of the ureter. Coloured drawings illustrating the above statements accompany the text which is to be found in the number of the *Archiv für Anatomie und Physiologie* of Professors His and Engelmann for March, 1903.

CAMBRIDGE SCIENCE SCHOOLS.

THE large lecture room of the engineering laboratories' new wing at Cambridge was the scene of an interesting ceremony on May 11th when a bust of the late Dr. John Hopkinson was unveiled. What Sir George Humphry and Sir George Paget were to Cambridge in the matter of a medical school that was Dr. John Hopkinson with regard to the engineering school of the University. In other words, it is hardly too much to say that he was the founder of the engineering school which is now flourishing at Cambridge. To have achieved a result such as this is, as Lord Kelvin observed in his remarks at the ceremony on May 11th, to have benefited, not only Cambridge University, but the world at large. The practical benefits which are spread through scientific training at a university are well recognised by men of business and it is an appropriate evidence of such recognition that the chairman of the Linotype Company, Sir Joseph Lawrence, should have presided at the unveiling of Dr. Hopkinson's bust, the bust itself being the gift of the company to the University of Cambridge. One thing that is often not recognised by business men is the pecuniary difficulty which the ancient universities find in providing for the necessary advances in scientific teaching. Professor Ewing told a very *àpropos* story on this point at the gathering on May 11th and we hope that his words may lead to an increase in the coffers of the science schools of the University of Cambridge, where the medical faculty does such good work and is so much in need of financial help.

RICHTER'S HERNIA.

"RICHTER'S hernia" or "partial enterocele" is the name applied to the condition when only a portion of the circumference of the bowel is included within the hernial sac. It was formerly confused with Littré's hernia—that is, a hernia of Meckel's diverticulum—but Sir Frederick Treves suggested the suitability of the application of the name of Richter to the partial enterocele, as it appears to have been clearly described by him in 1779. Mr. McAdam Eccles has pointed out, however, that Lavater wrote an account of this variety of enterocele in 1672, though his description was not published until 1755, and that therefore Lavater's name might reasonably be associated with this condition. The late Mr. J. W. Hulke made it clear that Littré described not only the hernia of Meckel's diverticulum, now called a "Littré's hernia," but also in 1714 a true partial enterocele, for he distinctly refers to the fact that the whole circumference of the bowel was not included. Thus it is clear that the honour of first recognising the condition must be shared, but as Littré's name is now applied to another variety of hernia and as Richter's name is usually given to partial enterocele it would probably be well to retain the present designation. The condition is not a mere pathological curiosity. So long as no strangulation occurs a partial enterocele is not to be distinguished from an ordinary enterocele, but it is when this variety is strangulated that the peculiar importance of the condition is seen, for in about two-thirds of the cases the signs and symptoms of strangulation are obscure or incomplete. The bowels may continue to act during the whole progress of the strangulation or they may be opened by aperients. Even persistent diarrhœa may occur. Inasmuch as frequently there is no blocking of the lumen of the bowel, tympanitic distension of the abdomen is rare; and even when the site of the hernia is examined it may be difficult to detect it, for often it forms a very small swelling. Some degree of vomiting is frequently present but it is usually not severe and is rarely feculent. In spite, however, of the mildness of the symptoms the mortality is very heavy, amounting in the 53 cases collected by Sir Frederick Treves to over 62 per cent. This heavy death-rate is in part to be accounted for by the obscurity of the symptoms, with consequent delay in operation, and partly to the tightness of the constriction. The hernia is usually of the femoral variety, for at the crural ring there especially exist the conditions required for the nipping of a part of the circumference of the gut. It is of interest to note that a large proportion of obturator hernias are partial enteroceles and this may help to account for the obscurity of the symptoms in that form of hernia. Richter's hernia is probably less rare than might be imagined from the number of recorded cases, but it is probably often unrecognised. In the present issue of THE LANCET (p. 1444) are the notes of two instances of this interesting lesion which were under the care of Sir William J Collins.

ANNUAL DINNER OF THE SANITARY INSTITUTE.

THE members and friends of the Sanitary Institute dined together on May 15th at the Hotel Cecil, London, the Duke of Cambridge, the President of the institute, being in the chair. In replying to the toast of the "Queen and Royal Family," proposed by the Duke of Northumberland, the Duke of Cambridge said that the work and welfare of the Sanitary Institute had always interested him and as long as he was granted health and strength he would be willing to promote its prosperity. "The Navy, Army, and Auxiliary Forces" was given by Sir Francis S Powell and was replied to by Sir Henry F. Norbury (Director-General of the Royal Navy Medical Department) who gave some interesting details concerning the increase in the navy. This toast was also acknowledged by Lieutenant-Colonel A. S Jones, V.C Sir Henry G. Howse, President of the Royal College of Surgeons of England, proposed the toast of "The Houses of Parliament" and pointed out that the members of the Sanitary Institute included eminent engineers, members of the House of Lords and members of the House of Commons, scientific men, and representatives of municipal authorities and of the medical profession The meeting together of these members of the Sanitary Institute must be useful in crystallising their views in regard to sanitary legislation. Lord Monkswell and Mr. Talbot, M.P., acknowledged the toast. In proposing the toast of "The Sanitary Institute" Sir William S. Church, President of the Royal College of Physicians of London, congratulated the institute on its flourishing condition. In the course of some interesting remarks on the history of sanitary legislation Sir William Church described how in the archives of the City of London there were some instructive accounts of the measures taken to benefit the health of the people. The beadles of the City were enjoined to perambulate the streets and to prevent swine straying, and further they were ordered to arrest all vagrant men because, as the directions went on to explain, these men might be the cause of spreading disease. He urged the Sanitary Institute to spread the knowledge of sanitary matters among the people and to continue holding congresses in provincial cities, thereby attracting general attention to the subject of hygiene. The institute had done good work in giving 470 lectures which were attended by upwards of 22,000 people. After Mr. W. Whitaker had briefly acknowledged the toast the company separated. Amongst those present besides the speakers were Sir H. Crawford, Sir S. Black, Sir A. Binnie, Major R. Ross, Dr. L. C. Parkes, and Dr. W. Collingridge.

POST-GRADUATE STUDY IN LONDON.

IT is satisfactory to hear that the Association of London Hospitals and Medical Schools, which offers such exceptional advantages for clinical study to qualified medical men, is still steadily increasing its scope. We are authorised to state that the London Hospital has now joined the scheme which is therefore complete so far as it embraces all the institutions recognised by the University of London for medical education—viz.:—*General hospitals:* Charing Cross, Guy's, King's College, London, Middlesex, St. Bartholomew's, St. George's, St. Mary's, St. Thomas's, University College, and Westminster. *Special hospitals:* The Brompton Hospital for Diseases of the Chest, the Hospital for Sick Children, Great Ormond-street, the London School of Tropical Medicine, the National Hospital for the Paralysed and Epileptic, and the Royal London Ophthalmic Hospital. The wealth of clinical material in London is almost incalculable but unfortunately its value for post-graduate instruction is materially diminished, partly by the extent of the area over which it is spread and partly by the lack of connexion between the various hospitals in which it is contained. The one difficulty, that of distance, is of course irremediable; the other, that of lack of coördination, is to a large extent met by the present scheme, and for that reason we wish it continued success. The fee is moderate (seven guineas for a three months' course and ten guineas for six months) and should offer no obstacle to those who wish to devote some time to clinical study in medicine, surgery, or any of the special departments Particulars may be obtained on application to the Secretary, the Associated Schools of Medicine in London for Post-Graduate Teaching, Examination Hall, Victoria Embankment, London, W.C.

THE PREVENTION OF DUST DISEASES.

THE Society of Arts is once again directing its attention to the means of protection available against diseases due to the inhalation of dust Under the terms of the Benjamin Shaw Trust the council of the society has just offered a prize of a gold medal, or £20, for the best dust-arresting respirator for use in dusty processes and dangerous trades. Specimens with full description may be sent in to the society's offices in John-street, Adelphi, until Dec. 31st next. Competitors must themselves look to the securing of any patent rights which they wish to retain. There is, of course, no lack of respirators already, but such as are actually in use are open to objections, not all of them very reasonable, perhaps, which seriously diminish their value. Male workers object to respirators because of their general inconvenience, while factory girls, like girls more happily situated, are often ready to sacrifice health to appearances Possibly, too, the old objection that lessened risk means lowered wages has still some force. The society aims at finding a respirator which shall be simple in construction, light, cheap, and sightly, one which can be worn for hours without interference with respiration, and one which will not permit expired air to be breathed again. An apparatus satisfying all these requirements would have a certain sphere of usefulness, but we are a little doubtful whether the society is working on the right lines. Even supposing that a thoroughly efficient respirator impermeable to dust were devised we fear that the difficulty of getting work-people to wear it would not be easily overcome. Even if worn it would afford no protection against poisonous vapours and while it might limit the field of pneumonokoniosis and enterokoniosis it would have no application to the important group of lesions included under the term dermatokoniosis. The plan of carrying on the work before an upcast shaft so that dust and vapours are at once borne away by a current of air seems rather the one deserving of encouragement.

RECENT DISCOVERIES ON THE CAUSATION AND TREATMENT OF HAY FEVER.

Three interesting contributions to the subject of the causation and treatment of hay fever have been recently published. In the *Berliner Klinische Wochenschrift* of March 2nd Dr. G. Rosenfeld of Berlin refers to the question of hay fever as caused by the pollen of certain flowers and adds to the list a plant hitherto unrecognised as a cause—viz., the plantus occidentalis which is found in bloom in the neighbourhood of Stuttgart from the middle of May to the end of June, during which time hay fever is prevalent in that locality. The symptoms of hay fever caused by it are of the usual type and can be reproduced by experimental insufflation of the pollen into the nostrils. In the *New York Medical Record* of March 28th Dr. Raymond Wallace emphasises the fact that a neurotic predisposition to the affection exists in persons who develop hay fever. Persons who are "naturally highly strung, excitable, irritable, neurasthenic, having 'nerves' which are literally 'on the surface,' are those who are more liable to this affection than are the more phlegmatic types." The element of periodicity which is generally observed in attacks indicates that a psychical factor is concerned in the etiology of hay fever as exemplified in the case of a patient who has had attacks on August 15th of one year and who began to suffer in subsequent years on the same date. A neurotic young woman, aged 25 years, known to Dr. Wallace, suffers regularly from three attacks per diem on certain days. Thus upon arising from bed she always anticipates an attack and it always comes on unless she can abort it by firm pressure upon the upper lip. In the afternoon at the lunch hour a second attack follows and at night on retiring to her bedroom the third attack occurs. Another case was that of a young man, aged 30 years and of neurotic constitution. He suffers from hay fever in a regular and periodic fashion. Under medical treatment he does not have more than four or five attacks during the day. When at work in his office he is seldom troubled with an attack. But if he is spending the evening in society his mind dwells upon the possibility of an attack and of the embarrassment likely to be caused. He then has two or three attacks and is compelled to leave the room. Dr. Wallace has found that strong sunlight will in some persons provoke an attack of hay fever with its attendant symptoms of sneezing, vaso-motor congestion of the nostrils, and coryza, the attack being caused reflexly by excitation of the vaso-motor centres through the optic nerve, and in the same way it has been observed that dust, pollen, and certain odours may act through the trigeminal and olfactory nerves and provoke an attack. The psychical element is, concludes Dr. Wallace, a factor of growing importance in many diseases and in hay fever it plays an important part. Dr. Dunbar, the physician in charge of the Institute of Hygiene at Hamburg, states in the *Deutsche Medicinische Wochenschrift*, No. 9, 1903, that he has succeeded in isolating the toxic substance from the pollen of grasses which is capable of producing hay fever in predisposed persons. He was thus able to reproduce attacks of the disease in winter by subcutaneous injection of a minute dose of the same. This toxic substance is not the ethereal or oily constituent of the pollen grains but is apparently, adds Dr. Dunbar, an alkaloidal body. The attack of hay fever produced by it is intense. An attempt was made to produce an antitoxic serum from the blood of animals inoculated with this toxin. After some trials this was successfully effected and in the course of his experiments he inoculated eight patients with hay fever by instilling into the eye finely-ground pollen grains suspended in water. In every case the physical and subjective symptoms of hay fever were reproduced in varying degrees of intensity. The new serum was then tested by mixing some of it with the pollen and applying the mixture to the eye. "The eye itched slightly and appeared congested," but these symptoms disappeared in less than 30 minutes. The serum was equally effective against the pollen of various cereals.

COUNTY COUNCILS AND ISOLATION HOSPITALS.

The Essex county council is apparently the first to take advantage of the Isolation Hospital Acts and to make grants systematically to the authorities which have provided isolation hospitals. Prior to the recent amending Act grants could only be made to hospitals erected under the Act of 1893, now grants can be made to any hospital, but the sanction of the Local Government Board is necessary if the hospital is erected out of current rates and therefore without the plans having received the approval of that Board. At the commencement of this year the Essex county council announced that it was prepared to make grants towards the maintenance of isolation hospitals and that applications were to be made before a given date. Applications were received from 17 out of the 19 authorities in the county which had provided hospitals. All these hospitals have been examined and reported upon by the county medical officer of health and the marks awarded range from 55 to 100, the latter being the maximum. In awarding the marks every point in connexion with the position, construction, and administration of the hospitals was taken into account, together with the adequacy of the accommodation for the districts served. The sanitary committee has adopted these marks as the basis upon which the grant shall be made and recommended that each authority should receive 2*s.* per mark per bed for the year ending March 31st, 1903. The best hospitals will therefore receive a grant of £10 per bed and the worst £5 10*s.* It is probable, however, that next year some other basis will be adopted, as the difference between the various hospitals is not sufficiently well marked to encourage the improvements and reforms which the county council wishes to see carried out. Of the 17 hospitals to which grants have been allotted six were erected out of current rates and therefore the approval of the Local Government Board will be necessary before the grants can be paid. These hospitals are all wood and iron structures of a so-called "temporary" character and it remains to be seen whether the Board will sanction grants to such hospitals. The possibility of a refusal is evidently recognised, as the sanitary committee recommends, if the Board's sanction is withheld, that no grant should be made to any hospital. The table prepared by the county medical officer contains a mass of interesting information. Amongst other items it appears that the permanent isolation hospitals in Essex have cost from £360 to £700 per bed to erect, and that the establishment and patients' expenses have varied from £28 to £167 per bed There can be no doubt that the attention which the county council is giving to this subject will ultimately result in a great improvement in the hospital accommodation and administration throughout the county

A STATE REGISTER OF TRAINED NURSES FOR POOR-LAW INFIRMARIES.

AT a conjoint conference convened by the Matrons' Council and by the Society for the State Registration of Trained Nurses on May 8th at 20, Hanover square, W., a paper was read by Miss Eleanor C Barton, matron of the Chelsea Infirmary, entitled "State Registration of Trained Nurses as it affects Poor-law Infirmaries" The writer of the paper seemed to be in favour of the establishment by the State of a register of trained nurses, but she advanced nothing in the nature of argument to support such a procedure on the part of the Local Government Board beyond the conjecture that "when the State registration is inaugurated and the present chaotic state of the nursing profession is at an end the trained and disciplined nurses of our metropolitan infirmaries, who have as yet hardly been appreciated as they ought to be, will form a large and valuable addition to the nurses of Great Britain" The paper almost failed to carry out the promise of its title, for it did not—except in the extract given above—show the manner in which State registration of nurses will affect the Poor law infirmaries The paper touched lightly, from the nurses' point of view, upon the various branches of infirmary work and it also enumerated the great teaching opportunities afforded by the nursing of the many aged patients and others suffering from chronic diseases found in the wards of the modern infirmaries but rejected from the wards of the hospitals With the actual statements contained in the paper we are quite in agreement, but underlying those statements there appeared to be two assumptions upon each of which we may make a few comments The first was that the Local Government Board has the intention of establishing in the near future a system of State registration for nurses, and the second was that there will be an examination conducted by a State appointed board of examiners So far as we can ascertain there is of the intention mentioned no evidence whatever Neither has it yet been clearly shown that the public and the authorities of the two great nursing institutions (the hospitals and the infirmaries) have arrived at an agreement upon the desirability of State registration of nurses We have reason to believe that certain of these authorities hold the opinion that it would be unwise to inaugurate a system of registration until a defined curriculum and a recognised examination have been established Granting that the Local Government Board had taken in hand the formation of a State register of nurses, there would still be little probability of the creation of a State appointed board of examiners A review of the action of the Local Government Board during the past few years will lead inevitably to the conclusion that there exists no predilection for examinations of nurses on the part of that Board. Women who have worked for 12 months in the sick wards of a workhouse and have received a small, indefinite amount of teaching are, without examination, to be accepted as qualified nurses by that Board The superintendent nurses appointed under the General Order of 1897 are only required to have had a course of instruction for three years They may have availed themselves of their opportunities to the smallest possible degree, for they have no examination to pass Even if they have tried to pass one and failed they will still be eligible for the posts of superintendent nurses It is true that in the report of the departmental committee upon nursing in workhouses recently issued there is a recommendation of a defined curriculum with a final examination, but there is nothing beyond the recommendation and the matter is treated in a vague unsatisfying manner, wanting in all indications of the scope of the curriculum, without suggestions as to the persons who are to arrange the details of the scheme, but with merely a stipulation that there shall be two independent examiners, one of them being a lady from a recognised training school We leave the subject with the observation that the "present chaotic state of the nursing profession" (the wording is not ours) may be brought to an end, but the organisation of the chaos will require the concerted action of the nursing authorities of the large training institutions, the Local Government Board is not likely to initiate a scheme that will give general satisfaction but it may sanction one

PHLEBITIS OF INFECTIOUS ORIGIN IN CHLOROSIS

VENOUS thrombosis is a rare complication of chlorosis and its pathology is not fully known In some cases it depends on phlebitis, which in its turn has been ascribed to microbes They have been found in the blood of the inflamed vein and in the general circulation, but in no case have they been found in the venous lesion Hence the importance of the following case described at the meeting of the Société Médicale des Hôpitaux of Paris by M Paul Sainton and M Andre Jousset A well developed girl, aged 18 years, was admitted to hospital on Feb 6th A fortnight previously she noticed œdema of the right ankle Soon pain in the position of the external saphenous vein followed She was pale and the skin was waxy white, slightly tinged with yellow There was marked œdema of the right foot, ankle, and calf A systolic, musical, almost whistling murmur was heard at the right border of the sternum. Over the left jugular vein near the clavicle vibration could be felt and a loud continuous *souffle* could be heard The appetite was diminished and there was constipation On Feb 13th the right thigh was swollen and was five centimetres in circumference more than the left and its superficial veins were well marked The pain was increased and situated in the position of the deep vessels of the limb With this extension of the phlebitis the general condition, previously good, changed There were slight pyrexia (an evening temperature of 101 3° F), malaise, and anorexia The urine become darker and contained indican The blood was very pale and of specific gravity 1052 (instead of 1055) The red corpuscles numbered 2,300,000 per cubic millimetre there was poikilocytosis, and the hæmoglobin index was 0 62. The white corpuscles numbered 10 000 per cubic millimetre On Feb 20th the swelling extended from the thigh to the abdomen and the course of the internal and external iliac vessels was tender At the same time the œdematous skin became "marbled' with fine varicosities of ecchymotic appearance, especially at the upper part of the thigh On Feb 22nd the patient complained of a stitch in the right side and at the base of the lung behind slight dulness and diminished respiratory murmur were found. On the following day she complained to the patient in the next bed that "she could not feel her left leg and yet felt pain in it." She turned several times in the bed, suddenly placed her hand on her chest, complained of being stifled, had an attack of severe dyspnœa without cyanosis, and died in half an hour At the necropsy the thyroid gland was found to weigh 15 grammes (instead of 25); the thymus gland was persistent and weighed 13 grammes (the normal weight in an infant) The aorta was narrow. The right pleural cavity contained 300 grammes of serous effusion and there were numerous subpleural hæmorrhages. In the right lung was a large conical infarct two centimetres in length. In the right ventricle, in addition to post-mortem clots, was a small white elongated non-adherent clot. The pulmonary artery contained clots which ramified as far as the smallest branches to the left superior and right inferior pulmonary lobes. In the inferior vena cava thrombosis began gradually at a distance of seven centimetres from the sacral promontory. *Into the left iliac vein the thrombosis did not extend* far, but from the right the clot could be followed through the external iliac, femoral, popliteal, internal saphenous, and profunda veins. In the lower part of the femoral vein there was suppurative endophlebitis. The spleen was very large and diffluent. The affected femoral vein and the spleen yielded cultures of virulent diplo-staphylococci pathogenic to the rabbit. This case goes to show that the phlebitis of chlorosis, like other forms of phlebitis, is of microbial origin.

THE POSITION OF THE PUBLIC VACCINATORS.

THE following resolutions were unanimously passed after full discussion at a meeting of the Liverpool Medical Club last week. A representative body of medical men, including general practitioners, consulting practitioners, and public vaccinators, were present :—

1. That vaccination should be under the direct control and supervision of the Local Government Board in London.
2. That the post of public vaccinator should be a permanent appointment and that he be debarred from private practice, and that no certificate of successful vaccination shall be accepted from any private practitioner unless it comes up to the Local Government Board standard.
3 That all private practitioners be supplied free of charge with lymph from the Local Government Board on application on the prescribed forms.

Dr. J. Kingston Fowler will give the opening lecture of the summer session at the Hospital for Consumption and Diseases of the Chest, Brompton, on Wednesday, May 27th, at 4 P.M. The subject of the lecture will be the Diagnosis of Intrathoracic Tumours. We doubt if members of the medical profession sufficiently appreciate the value of the course of lectures delivered at this hospital. The amount of material at the disposal of the physicians and assistant physicians is unparalleled, so that the lectures are of an extremely interesting character. Their practical value is known to those who attend them but the attendance might well be increased.

Professor E. A. Schafer, F.R.S , will read a paper on the Phenomena attending Death from Drowning and the Means of promoting Resuscitation in the Apparently Drowned in the rooms of the Royal Medical and Chirurgical Society, 20, Hanover-square, W., on Tuesday next, May 26th, at 8.30 P.M. The paper will be illustrated by means of the epidiascope. The council will welcome to the meeting any member of the medical profession or medical student interested in the subject.

The Prince and Princess Christian of Schleswig-Holstein have made the following appointments: Sir Francis Henry Laking, Bart, G.C.V O., to be Physician in Ordinary, and Mr. William Fairbank to be Surgeon-Apothecary in Ordinary to their Royal Highnesses; and Mr. Willie Netterville Barron to be Surgeon-Apothecary to their Royal Highnesses' Household.

THE Medical, Surgical, and Hygienic Exhibitors' Association, Limited, will hold its Seventh Annual Exposition of Professional Exhibits at the Queen's Hall, Langham-place, London, W., on June 2nd, 3rd, 4th, and 5th, 1903, from 2 P.M. to 10 P.M. each day. Music will be rendered by a select orchestra every afternoon and evening.

AT the dinner of the Glasgow University Club, London, to be held on Friday, May 29th, the chairman, the Right Hon. George Wyndham, M.P., will be supported, among others, by Earl Lytton, the Right Hon. James A. Campbell, M.P., Mr. Scott Dickson, K.C., the Solicitor-General for Scotland, and Mr. W. J. Galloway, M.P.

THE KING has granted to Dr. Cyril Goodman His Majesty's Royal licence and authority to accept and to wear the Insignia of the Third Class of the Imperial Ottoman Order of the Medjidieh, conferred upon him by His Highness the Khedive of Egypt, in recognition of his valuable services to the Egyptian Government.

MEETINGS of the Central Midwives Board were held on May 7th, 12th, and 14th. The drafting of the rules under Section 31 of the Midwives Act, 1902, was completed and the secretary was instructed to forward a copy to the Privy Council for its approval, together with some draft "Suggestions to County Councils."

THE forty-third annual dinner of King's College, London, will be held at the Holborn Restaurant, on Monday, June 22nd, the Bishop of Exeter in the chair. All communications should be addressed to Mr. John Chapman, honorary secretary of the committee.

THE annual conversazione of the Medical Society of London was held on May 18th, Mr. A. Pearce Gould, the President, being in the chair. The oration was delivered by Sir William H. Bennett, K.C.V.O., and is published in full on p. 1423 of our present issue.

AMONGST the latest contributions received at the Bank of England for King Edward's Hospital Fund for London is the sum of £100 from the executors of the late Archbishop of Canterbury for annual subscription payable in 1902.

LEPROSY AND FISH-EATING.

LORD GEORGE HAMILTON, M.P., Secretary of State for India, presided over a meeting held on May 15th at the Medical Graduates' College and Polyclinic, Chenies-street, London, W.C., to hear an address by Mr. Jonathan Hutchinson on the results of his recent journey to India for the investigation of leprosy. In opening the proceedings he referred to the facts that leprosy had largely diminished in India during recent years and that the Commission on Leprosy which was appointed some years ago to inquire into the causation of the disease was not unanimous in its conclusions.

Mr. HUTCHINSON, of whose address the following is an abstract, said : My Lord, Ladies, and Gentlemen,—May I in the beginning state that there is in connection with this institution a standing committee for the investigation of leprosy and that that committee will meet on May 21st? I went to India with a very strong conviction which I have held for many years to the effect that the fish theory was the only one which would explain the prevalence and the disappearance of leprosy in various places. The commission to which your lordship has alluded was formed in 1890 and the members visited India. They did not neglect the investigation of the question of fish-eating and they returned a somewhat adverse verdict to it based on the fact that a certain number of lepers denied ever having eaten fish. My object in going to India was to see whether that objection could be got over. Since this commission visited India the fish hypothesis has assumed a somewhat modified aspect in that we fully recognise what is called commensal communication of leprosy—namely, that it is communicable by food from the leper's hands conveying the bacillus as it seems directly into the stomach from the leper's hands. That tends to explain exceptional cases in which a leper may deny that he has ever eaten fish, for he may have acquired his leprosy by this commensal communication without eating fish. Again, there are innumerable different languages in India and the patients very often misunderstand what is said to them. If asked blankly, "Have you eaten fish?" they might suppose that the question probably was, "Have you eaten fish taken out of the stream?" They might have *entirely forgotten the peculiar appearance that fish is apt* to assume. Under certain dried conditions fish does assume very different appearances, and might very often not be recognised as fish. Here is a specimen of Indian fish preserved in such a way that any person might eat it without knowing that he was eating fish. *Moreover the* number of different names and words which are applied to dried and salt fish is very great. I found at several places that not only amongst the patients, but also amongst those who were their superintendents and caretakers, the idea *of salt fish meant fish taken out of the salt sea. That was* not what I meant; I meant any kind of fish preserved in salt. I very much wished to excite popular interest and inquiry into the subject. Therefore I wrote letters to the Indian medical journals and to the Indian press generally—that is *to say, the non-medical press—to state what my opinions* were with regard to leprosy and asking for information from all quarters. I was anxious to direct public attention to the dangers of eating bad fish and in that way to diminish the prevalence of leprosy, even though it *might be without convincing any medical friends, or all of* them at any rate. I addressed a letter to the presidents of all the medical colleges in India and I asked to be permitted to hold in their colleges a meeting to which all medical men in the district should be invited and before *which I should expound my views. In every place the* president of the medical college responded to my request and convened a meeting and at each of these I gave an address. In this way there was full opportunity for any criticism.

Various persons have said to me over and over again: "Leprosy disappears before civilisation; you need not trouble yourself about fish." My reply is that it recedes under many conditions of advancing civilisation, but not under all. For instance, there is plenty of leprosy in the West Indian Islands *and in* Spain *and Portugal,* while in Cape Colony it is steadily advancing, and if there are benefits to be derived from mere segregation Cape Colony ought to have felt them. The advocates of the fish theory allege broadly that the one factor of importance in the *decline of leprosy* is the disuse of badly *preserved fish*, and that the advance of civilisation acts by supplying different articles of food and thus diminishing the consumption of bad fish. I have often been asked why decomposing meat might not also be a c[illegible]d the reply [illegible]as long been habitual to eat decomposing meat but in which no leprosy occurs. A Kaffir in Natal will eat the flesh of a dead ox, however advanced in decomposition it may be, but from time immemorial they had no leprosy in Natal until they had communication with Cape Colony, where the people eat salt fish, and that is within the last 60 years. The fish hypothesis assumes that really fresh fish and really well-preserved fish are both alike innocuous, and that cured or uncured fish in commencing decomposition may occasionally contain ingredients which become effective in the causation of leprosy. It is not the excessive use of fish, but the accidental reception of a specific ingredient in connexion with fish which determines the occurrence of the disease. The belief that leprosy is communicated by direct inheritance was entirely discredited by the evidence of the commission and there is very much other evidence which leads us to attach no importance to the belief that it is so communicated. The hypothesis of commensalism is very much more plausible. At Lahore I saw a baker who came amongst the general out-patients of the hospital for advice because he had got very sore hands and this was a great impediment to him in making bread He was a leper unquestionably, and his hands had leper's sores upon them. We can see at once the possibility of contagion in that direction.

Having made these explanations, I now proceed to my argument, one point of which will be that there is no part of India in which the fish hypothesis is not possible. My journey was on the south-east coast, stopping at Madras, Calcutta, Darjeeling, and then across the whole north of Hindustan, going as far north as Lahore and passing down to Mysore and Bombay. *Leprosy is scattered all over India;* there is no place which is absolutely free from it, and it prevails to a very large extent excepting in a very few places. *Tables have been prepared which show that five per* 10,000 is the average prevalence of leprosy throughout the whole Indian population. There are no places in India where the fish hypothesis is impossible on account of there being no fish to eat. I will read you a brief quotation from *the Imperial Gazetteer in India, by Sir William Hunter. He* has written as follows: "All the waters of India, the sea, the rivers and the tanks, swarm with a great variety of fishes, which are caught in every conceivable way, and furnish a considerable proportion of the food of the poorer *classes.* They are *eaten fresh* or as *nearly fresh* as may be, for the art of curing them is not generally practised, owing to the exigencies of the salt monopoly." Two districts, however, were pointed out to me as being those in which the fish hypothesis would not apply on *account of the great dif*[illegible] smallness of its supply. T[illegible] It is an inland district sit[illegible] sandy district and over anc[illegible] by men who were well experienced and had lived in that *neighbourhood that if I would go to Chota Nagpur I should* find a district in which leprosy prevailed and fish was not obtainable. The other locality of which the same thing was asserted was the sub-Himalayan country in the north of Hindustan. I was assured that the people do not get fish *there and yet they have leprosy. The Chota Nagpur* district is some distance from the sea and has but few rivers. Its leper asylum is a little town. I went there, of course, and met the Rev. Dr. Harn, a medical doctor as well as a theological one, and I said that my object *in coming was to question those of the lepers in the* asylum—more than 500 in number—who said they had never eaten fish. Dr. Harn replied: "I have not one in the asylum who has not eaten fish. They have all eaten fish habitually." Dr. Harn's resident medical officer, who was *more familiar with the lepers themselves than Dr. Harn* himself, added to this. "Not eaten fish? Why, a great many of them think that fish has caused it. Numbers have left off eating fish in the belief that it had been the cause of the leprosy and made it worse." So much for Chota Nagpur. *Why had my friends who said that there was no fish been so* certain? They had travelled through the district rapidly in the dry season and they did not realise that in the rainy season every pool and river and brook was full of water and that there was plenty of fish to be got. In this leper asylum, *of which it was asserted* in Calcutta that none of the inmates had eaten fish, the fact was that fish was given regularly for meals. And at an adjacent asylum under the management of missionaries they said: "Yes, there is plenty of fish-eating here and we get our fish from Puralia, and we cannot conceive how anyone could have told you that." That must be taken as a type of a great many places where there is an elevated sandy district. I visited Puralia market and I saw the fish there. As to the sub-Himalayan districts, in talking with various sportsmen in the army and with people who had been frequently there and had themselves been accustomed to fish they said to me: "No fish in these sub-Himalayan districts? The streams all swarm with them. All the natives catch fish and there is plenty of fish." One gentleman said: "I go to fish there myself and I assure you the men are all very eager to eat fish, and they take the excess of any fish I catch and they salt it and keep it and then eat it in a condition in which I assure you I would not eat it." *Dr.* Hooker, who travelled several years in Sikkim (and that is in the Himalayan districts very nearly, a little to the west of Darjeeling), has stated: "On Kalapance Road (right under the foot of the Himalayan mountains) we passed crowds of market people laden with dried fish in a half putrid state which scented the air for many yards; they were chiefly carp caught and dried at the foot of the hills." I went to Darjeeling myself and there I found abundant fish in the market at a very considerable elevation above the sea and in full sight of the Himalaya mountains. The commission also reported that it was astonished at finding there was plenty of fish to be got in this district. I must now pass on to ask if there is any religious creed in India to which the suspicion of eating fish will not apply. The chief sects in India—I must not attempt detail because there are so many sects—are the Hindoo and the Mahomedan. The Mahomedan will eat anything except pork and one or two other white meats; *for instance,* I think he will not eat hare, but he will eat fish freely. A Hindoo lives to a very large extent on rice. He would not eat any flesh of cows; that would violate a sacred rule, but he will eat almost any other kind of meat and he will eat fish, although he has a sentimental feeling that it is better and more virtuous to live on vegetable than on animal food. Certain forms of Brahminism fully allow of fish-eating and it is enjoined in the ritual that they shall eat fish at certain times. The very highest caste Brahmins will not eat animal food, but even amongst them the free use of animal food, including fish, is allowed up to the age of nine years, when the children assume the sacred thread, and afterwards they must not eat animal food. Again, the Jains form a very ancient sect, as old as Buddhism, and they are rigidly against the taking of life in any form. They go about with a little piece of muslin in front of their mouths to prevent insects getting into their mouths, not that they wish to protect themselves against the disagreeableness of the insects but they wish to protect the insect's life. Yet I think he would be a bold man who felt sure that no Jain ever ate fish. Hindoo sentiment with regard to fish may be said to be somewhat thus: That every Hindoo would prefer to say that he had not eaten fish, and if you go to a leper asylum to question them as to whether they have done so, it is very much as if you should institute an inquiry as to spirit-drinking in an English asylum. Therefore, if you ask Hindoos in a leper asylum as to fish-eating you must expect various replies, according to the moral courage of the man and according to what he thinks you want him to say. Whilst I was at Calcutta I received a postcard stating that if I would go to a certain asylum in the North of the Punjab district (Nicodar) I should find an asylum containing 100 persons not one of whom had ever tasted dried fish. I consulted the Viceroy about the matter and he very kindly sent a telegram asking that I should be supplied with full information. The resident medical officer therefore prepared a full statement, giving the names of all the lepers in the establishment, stating their age, sex, whether they had relatives who had leprosy, and giving one column, which was the most important of all, headed, "Have you ever eaten fish?" Now, in this schedule which was presented to me when I arrived at the asylum there were 40 men put down as not having eaten fish. So I thought that I must give up the fish theory altogether if this could be substantiated I therefore proceeded to question the inmates individually. The first man who was brought before me firmly and persistently avowed that he had never eaten fish. He admitted that his father and mother ate fish habitually and that there was plenty of fish in his village, that his brothers and sisters ate fish, but that he had never tasted it because he did not like it. I then asked the resident medical officer to let me see another, but he replied: "There is not another, they all say they eat fish." That was the fact, there was not another man to be produced to say that he had not eaten fish. This, however, did not apply to the women. A woman who has said a thing will stick to it and all these women declared that they had never eaten fish. Therefore it was quite possible that in all of them it was a matter of commmensal contagion. At Bombay I was supplied with a report of the particulars of the Bombay Leper Asylum, the Matunga Asylum, and in this report among the columns showing the religion or race to which the patients belonged there was a column headed "Salsette Christians," a term which simply means the Christians living in the island of Salsette, an island close to Bombay and a great fishing centre. The Salsette Christians are Roman Catholic Christians. They were converted in the days of the Portuguese possession by the Portuguese Jesuits and they have continued ever since as a sect. The Bombay Leper Asylum receives patients from all parts of the Presidency without any selection and it has 500 inmates. A great number of them are Hindoos, the Hindoos being in superior numbers there, but the Salsette Christians in the asylum were very much in excess of their ratio to the population. The Calcutta asylum, the Madras asylum, and the asylum at Tantaran all show just the same sort of thing—an enormous preponderance of Christians. Of course there is a fallacy there, as there is a fallacy in all statistics, that inmates of the asylums may not represent the prevalence of leprosy in the community, but it is perfectly fair to take the records of the asylums as some basis for estimation of the presence of leprosy in the whole of the population. Let it not be suggested that there is anything in the habits of a converted native which tends to degradation. The change which native Christians experience so far as leprosy is concerned is, I am convinced, simply one of diet. In the case of all of them the race prejudice against fish is removed and in the case of the Roman Catholics it is replaced by a sort of compulsion to eat it. Having thus reviewed the evidence which I have accumulated in support of my theory concerning the causation of leprosy I may add that in my opinion the removal of the salt tax will be an immense boon to the community in various ways and that it will tend to prevent the prevalence of the disease.

Sir William H. Broadbent moved a vote of thanks to Lord George Hamilton for presiding. This was seconded by Dr. C. Theodore Williams and carried.

Lord George Hamilton admitted that the salt tax was heavy and pointed out that it must remain until some other source of revenue could be found. Though the tax had been reduced he believed that the extra consumption which the reduction would lead to would prevent any loss in the revenue. The heavy salt tax had, in his opinion, restricted fish-curing but he had not previously realised that there was any connexion between a heavy salt tax and the prevalence of leprosy.

The proposed discussion was adjourned to the next meeting of the Standing Committee of the Polyclinic on Leprosy.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An extraordinary Comitia was held on May 14th, Sir William Selby Church, Bart., K.C.B., the President, being in the chair. Dr. W. H. Allchin acted as registrar in the absence through illness of Dr. E. Liveing.

The following gentlemen who had been elected at the previous Comitia were admitted as Fellows of the College: Dr. A. P. Beddard, Dr. E. Cautley, Dr. J. S. Collier, Dr. B. E. Dawson, Dr. E. Goodall, Dr. W. Gordon, Dr. A. M. Gossage, Dr. L. Humphry, Dr. R Hutchison, Dr. J. A. Lindsay, Dr. A. Morison, Dr. F. J. Poynton, Dr. G. A. Sutherland, Dr. W. W. H. Tate, and Dr. StClair Thomson.

The Registrar (Dr. Allchin) proposed, and the Second Censor (Dr. G. V. Poore) seconded, the enactment for the first time of the following by-law:—

That Dr. George Francis Angelo Harris, elected a Fellow on April 30th, being resident in India, be admitted *in absentiâ*, any by-law to the contrary notwithstanding.

A communication was received from the Liverpool University Committee requesting the College to appoint a representative to be a member of the court or supreme governing body of the University.

The President moved from the chair that the request be granted and the proposal having been accepted by the College nominated the treasurer (Sir Dyce Duckworth) as the representative of the College.

Sir Dyce Duckworth consented to act.

Dr. P. H. Pye-Smith, the representative of the College at the recent International Congress of Medicine held at Madrid, presented his report and a vote of thanks was given to him for his services.

The President then dissolved the Comitia.

MEDICINE AND THE LAW.

The Medical Profession and Proprietary Medicines.

A very curious dispute has been ventilated at Liverpool in the court presided over by Sir Samuel Hall, K.C., vice-chancellor of the County Palatine of Lancaster. A firm of wholesale druggists sued a manager in their employment for moneys which they alleged that they had paid to him for the benefit of the Liverpool Throat Hospital, of which he had been for some years honorary treasurer. The moneys arose from royalties upon certain throat pastilles prepared by the druggists according to a formula of Mr. John Bark who, being a member of the staff of the hospital, had apparently handed the prescription to Mr. Jones, the honorary treasurer. The wholesale druggists arranged to produce and to sell the pastilles, paying a royalty of 6*d*. per pound to Mr. Jones, and the sales were such that the royalty in a single year amounted to £800. The agreement under which the payment of the royalty was made formed the original subject of the dispute, the druggists (Messrs. Evans and Sons) alleging that they paid it to Mr. Jones as treasurer of the charity, while Mr. Jones contended that he accepted it as proprietor of the formula which he claimed to have received as a gift from Mr. Bark. It was found by the court on a previous occasion that Mr. Jones had received the money in his hands in a fiduciary capacity and the recent hearing was in consequence of the medical men connected with the hospital, of which some of them were apparently trustees, pointing out that they were unable to give their services to a charity deriving profits from the sale of a proprietary medicine Considerable discussion appears to have taken place and an injunction was even sought against the medical men to restrain them from withdrawing, but ultimately a new scheme for the disposal of the fund was ordered to be drawn up with the consent of the Charity Commissioners and presumably the trustees who will eventually handle it will not be members of the medical profession. The report in the *Liverpool Post* of the proceedings upon the second occasion on which the matter came before the court does not afford a detailed account of several points which might be of interest to the medical profession. A good deal, however, would seem to have been said in the course of the discussion as to the importance of maintaining the secret of the prescription undivulged and the representative of the Attorney-General of the Duchy of Lancaster seems to have argued that medical men who were trustees for the charity were bound, in conformity with the contract under which the druggists made the pastilles, not to publish the formula. It would appear, therefore, that it was found that the druggists merely made up a prescription and sold it under a promise that as far as secrecy could give them a monopoly they alone should make the articles in question. This would be easier to understand than the proposition that Mr. Bark had or had ever claimed to have any proprietary right in a formula of his devising, or that any such alleged right had been transferred to Mr. Jones either as trustee or otherwise. The medical men connected with the hospital acted with obvious propriety.

Abortion and Murder or Manslaughter.

An abortionist was recently convicted on the Northern Circuit of manslaughter and sentenced to 15 years' penal servitude. The precise terms in which Mr. Justice Lawrance summed up the case to the jury are not yet fully reported, but he appears to some extent to have followed the summing up of Mr. Justice Bigham in R. v. Whitmarsh (62 Justice of the Peace, 711) and to have instructed the jury to the effect that if they should be of opinion that the prisoner could not as a reasonable man have expected death to result from his act they might find a verdict of manslaughter. A jury is prone to avail itself in such a case of any loophole which will enable it to acquit upon the capital charge. It is worthy of note that if Mr. Justice Bigham's statement of the law is correct he qualified it with reference to the case before him by others which clearly intimated to the jury that it was their duty to convict of murder. He said, amplifying his other observations, "If they should be of opinion that the prisoner could not as a reasonable man have expected death to result from his acts they might find a verdict of manslaughter"; and in another passage, "If the prisoner as a reasonable man could see no possibility of death, then you can find a verdict of manslaughter," and he spoke of the extreme remoteness of the possibility which would justify the milder verdict. In this case the jury found Whitmarsh guilty of murder.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on May 14th, Sir HENRY G. HOWSE, the President, being in the chair

Sir Francis Henry Lovell, C.M.G., was introduced, signed the by-laws, and was admitted a Fellow of the College.

Mr. Thomas Crisp English was introduced and the President handed him a cheque for the amount of the Jacksonian prize for the past year together with a document declaratory of the award.

Mr. Louis Bathe Rawling was introduced and the President handed him a cheque together with a certificate recording the Council's appreciation of the merits of his dissertation for the Jacksonian prize.

Mr. Kenneth Weldon Goadby was introduced and the President handed him a cheque for the amount of the John Tomes prize together with a document declaratory of the award.

It was resolved that diplomas of Membership should be issued to 109 successful candidates.

As recommended by the Court of Examiners an alteration was made in the regulations for candidates for the Diploma of Fellow so that Paragraph 7, Subsection II., Section III. shall read:—

> 7. Of having attended a course of lectures on biology at a recognised medical school or of having passed an examination in this subject at a recognised university.

It was resolved to issue diplomas of the Licence in Dental Surgery to 54 successful candidates.

A letter was read from the London County Council asking the College to suggest the names of well qualified pathologists to make post-mortem examinations and to give evidence in special inquest cases. In reply it was resolved to send the following letter:—

> The Council of the Royal College of Surgeons of England, while agreeing with the London County Council that it is desirable that pos [illegible] be [illegible] in [illegible]

The President was requested to communicate with a Member of the College to whose circular attention had been drawn.

A letter was read from Mr. G. H. Makins and Mr. F. C. Abbott, honorary secretaries to the MacCormac Memorial Committee, stating that a marble bust of the late Sir William MacCormac had been executed by Mr. Alfred Drury, A.R.A., for St. Thomas's Hospital and that the subscribers desired to offer a replica of the bust to the Royal College of Surgeons of England in commemoration of Sir William MacCormac's long and honourable connexion with the College. The offer was accepted with the best thanks of the Council to the subscribers.

A letter was read from Mr. Edmund Owen reporting his attendance as the representative of the College at the Fourteenth International Congress of Medicine held at Madrid in April last. A vote of thanks was given to Mr. Owen for his services.

A letter was read from the secretary to the Liverpool University Committee stating that the Lords of the Privy Council had advised His Majesty to grant a charter incorporating a university in Liverpool and asking the Council of the Royal College of Surgeons of England to appoint a Member of the Court (the supreme governing body of the University) as provided in the charter as drafted for the approval of His Majesty.

The PRESIDENT stated that a vacancy on the Court of Examiners occasioned by the retirement of Mr. R. J. Godlee would be filled up at the ordinary meeting of the Council in June.

A committee was appointed, in response to a request of the Royal College of Physicians of London, to confer with representatives of that College as to any alterations that may be desirable in the regulations for the First Conjoint *Examination.*

A letter was read from the General Medical Council, accompanied by a copy of the report of the visitors on the final examinations of the Conjoint Board. The report was referred to the committee of management to consider and to report.

PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS.

STAFFORDSHIRE.

AT a meeting of the sanitary committee of the Staffordshire county council held last February it was resolved—

> That the county medical officer of health be instructed to report upon the need in this county for the provision of a sanatorium or sanatoria for the treatment of phthisis and as to the steps, if any, which the county council may advantageously take in order to further or promote a scheme having such an *object in view.*

Dr. George Reid, the county medical officer of health, has therefore now presented a report, in the early part of which he states that in Staffordshire, excluding county boroughs, the mean annual number of deaths from tuberculosis during the past ten years was 805 and as the mean duration of the illness when fatal is from two to three years there were probably at least 2000 patients in the administrative county. Evidence of the preventable nature of the disease was afforded by the fact that during the last 40 years and coincidently with the growth of sanitation the death-rate from this cause in England and Wales had decreased greatly. In the period 1861-65 the tuberculous deaths per million persons living were 2526, but in the period 1881-85 the proportion fell to 1830 and in 1891-95 it further fell to 1461. What was known as the open-air treatment had been practised on a considerable scale for a good many years in Germany and some three or four years ago the movement extended to this country. Dr. Reid here quoted a table which was included in the appendix to Dr. A. Latham's prize essay and which will be found in THE LANCET of Jan. 3rd, 1903, p. 30, col. 1. He then described the details of a scheme which had been under consideration by the county council of the West Riding of Yorkshire, according to which for a hospital to accommodate 50 patients (35 men and 15 women) the initial establishment cost would be £26,100 and the annual expenditure would be £3511.

If a county council desired to take part in the providing of a hospital there were several methods which it might adopt. For example, its machinery might be used merely in an initial capacity with the view of obtaining what was wanted by the help of philanthropic persons, as was done in Worcestershire. Or it might endeavour to induce local authorities to unite for the purpose, with or without a promise of financial help from the county funds. On the other hand, the council might undertake the whole responsibility, structural, administrative, and household, and provide the necessary funds from the county rate. Dr. Reid did not advocate any of these arrangements. He, however, strongly recommended a scheme which he had outlined a considerable time ago and which was similar to the system afterwards approved of by the West Riding county council By such a scheme every authority in the administrative county, through the county rate, would contribute *pro rata* to the cost of the hospital and each authority might make use of the hospital on guaranteeing the payment of, say, £1 per patient per week, or possibly less. It would rest with the local authority as to whether it would find the whole of this amount, or whether part or the whole of it might be charged to the patient or subscribed by charitable persons, and in all probability funds would also be forthcoming from sick clubs.

It was desirable on economical grounds that the whole county should be served by one institution. The ideal site for the purpose would be on the south-western slope of a hill where the subsoil was dry and porous. The majority of the patients should have separate sleeping-rooms, but there might be one or two rooms with two or three beds in each. Whether the structure should be of a permanent or temporary character was a question about which there was much difference of opinion. Dr. Reid considered that a hospital containing 50 beds and standing on a site of 30 acres might be built and furnished for a capital expenditure of £19,900 and that the annual expenditure might be put at £2407. To this estimate there would have to be added the sum of £1 per bed per week (£2600 a year), for which it had been already suggested that the local authorities should be responsible. He was of opinion that the value of sanatoriums in the modern treatment of pulmonary tuberculosis was not merely curative for they were also educational centres where patients were taught the simple rules by which their recovery might be promoted and by which the risk of infection being conveyed to others might be avoided. To accomplish this much a residence in the institution of from six to eight weeks would probably suffice and in that way an institution of 50 beds would be capable of receiving 300 patients annually.

MANCHESTER.

At the annual meeting of the friends of the Manchester Hospital for Consumption good progress with the building of the Crossley Sanatorium at Delamere was reported. It was also stated that the first £50,000 of the £100,000 wanted as an endowment had been reached One or two points of interest came out in the course of the proceedings. The large proportion of "housewives" among the 11,300 outpatients was referred to as showing the pernicious effects of in-door employments and Mr. Crossley went on to speak of one of the important, but as yet unsolved, problems—namely, the future of the patients after leaving hospital and the finding of suitable employment. One scheme he had dimly in his mind was to send them across the sea, for he was told that in Tasmania "land was cheap and consumption unknown." There was an urgent necessity for continuing the open-air life that had led to cure, but in the case of town populations the problem seemed to be almost insoluble.

THE ROYAL SOCIETY'S CONVERSAZIONE.

SIR WILLIAM CROOKES'S DEMONSTRATION OF THE EMANATIONS OF RADIUM.

THE contributions to science during the past year have been of more than ordinary interest and the result has been a more than usually attractive exhibition in the rooms of the Royal Society on the occasion of the annual conversazione which was held on May 15th. The fact that the greater part of the council room, duly darkened, was allotted to Sir William Crookes made it fairly certain that this distinguished chemist was taking the opportunity of demonstrating the properties of that mysterious substance radium. The exhibit attracted the greatest interest and in spite of an alteration having been made this year for the first time in the day of holding the conversazione there was a very large and brilliant gathering present, the company being received by the President, Sir William Huggins, K.C.B.

In reviewing in our columns the work contributed by scientific men during the past few years we have frequently had occasion to direct our readers' attention to the remarkable results promised by the study of that property of certain elements known as radio-activity of which radium is now the most remarkable example. We may regard Sir William Crookes's recent statement as the most authoritative announcement upon this subject and the following is his striking description given to the Fellows of the Royal Society and their friends during the demonstration. The emanations from radium, he says, are of three kinds, one set is the same as the cathode stream now identified with free electrons—atoms of electricity projected into space apart from gross matter—identical with matter in the fourth or ultragaseous state, Kelvin's satellites, Thomson's corpuscles or particles, disembodied ionic charges retaining individuality and identity. Electrons are deviable in a magnetic field and are shot from radium with a velocity of about two-thirds that of light, but are gradually obstructed by collisions with air atoms. Another set of emanations from radium are not affected by an ordinarily powerful magnetic field, and are incapable of passing through very thin material obstructions. They have about 1000 times the energy radiated by the deflectable emanations. They render air a conductor and act strongly on a photographic plate. These are the positively electrified atoms Their mass is enormous in comparison with that of the electrons. A third kind of emanation is also produced by radium besides the highly penetrating rays which are deflected by a magnet: there are other very penetrating rays which are not at all affected by magnetism. These always accompany the other emanations and are Roentgen rays—ether vibrations—produced as secondary phenomena by the sudden arrest of velocity of the electrons by solid matter, producing a series of Stokesian 'pulses' or explosive ether waves shot into space. These rays chiefly affect a barium platinocyanide screen and only in a much feebler degree zinc sulphide. Both Roentgen rays and electrons act on a photographic plate and produce images of metal and other substances inclosed in wood and leather and shadows of bodies on a barium platinocyanide screen. Electrons are much less penetrating than Roentgen rays and will not, for instance, show easily the bones of the hand. A photograph of a closed case of instruments is taken by the radium emanations in three days and one of the same case by Roentgen rays in three minutes. The resemblance between the two pictures is slight and the difference great. The actions of these emanations on phosphorescent screens is different. The deflectable emanations affect a screen of barium platinocyanide strongly, but one of Sidot's zinc sulphide only slightly. On the other hand, the heavy, massive, non-deflectable positive atoms affect the zinc sulphide screen strongly and the barium platinocyanide screen in a much less degree.

If a solid piece of radium nitrate is brought near the screen and the surface is examined with a pocket lens magnifying about 20 diameters scintillating spots are seen to be sparsely scattered over the surface. On bringing the radium nearer the screen the scintillations become more numerous and bright, until when close together the flashes follow each other so quickly that the surface looks like a turbulent luminous sea. It seems probable that in these phenomena we are actually witnessing the bombardment of the screen by the positive atoms hurled off by radium with a velocity of the order of that of light; each scintillation rendering visible an impact on the screen and becoming apparent only by the enormous extent of lateral disturbance produced by its impact. In the same way, individual drops of rain falling on a still pool are not seen as such, except by reason of the splash they make on impact, producing ripples and waves in ever-widening circles. A convenient way to show these scintillations is to fit the blende screen at the end of a brass tube with a speck of radium salt in front of it and about a millimetre off and to have a lens at the other end. Focussing, which must be accurately done to see the best effects, is accomplished by drawing the lens tube in or out Sir William Crookes proposes to call the little instrument designed for this purpose the "Spinthariscope," from the Greek word *σπινθαρίς*, a scintillation.

A very interesting experiment was shown by the Rev. F. J. Jervis Smith demonstrating the effects of a high-pressure spark gap used in connexion with an inductor of the Tesla type and also in connexion with a radiator of Hertzian waves. The discharge at the terminals is augmented when the air or gas in the spark-gap globe is subjected to pressure by means of a pump. The spark readily perforates and cuts plate-glass placed in oil with conductors on each side, but intense as the spark is it has very little physiological effect—that is to say, only a pricking sensation is experienced when the spark passes between the terminal and the knuckle of the hand. A simple device for controlling and regulating spark discharges was exhibited by Mr. Alfred Williams. In his experiments he showed how by the use of a shunt or of plates of high resistance the field in a spark-gap can be so influenced that the discharges are made more regular and placed under better control for therapeutic and wireless telegraphy purposes. Sir Oliver Lodge and Dr Alexander Muirhead demonstrated the working of their new coherer as applied to wireless telegraphy. The coherer is automatic and consists of a steel wheel which rotates so that its edge touches a pool of mercury through a film of oil. An excellent method for the detection and estimation of minute quantities of arsenic in beer and brewing materials was demonstrated by Professor Thorpe of the Government Laboratory and his assistants. The apparatus consists of an electrolytic cell in which the hydrogen is generated from acidulated water to which has been added the suspected beer by means of the electric current. A little amyl alcohol is added to prevent frothing. The gas is subsequently dried and passed through a heated glass tube when the arsenic is deposited.

Dr. Allan Macfadyen and Mr. Sydney Rowland demonstrated the methods which they have used for the past four years in studying the intracellular toxins and ferments of bacteria and other cells. From these and other researches it has become evident that there exists a distinct class of toxins and ferments which are contained and operate within the cell or bacterium in contra-distinction to the now well-known class of toxins which are extracellular—i.e., *extruded during life* from the cell into the surrounding medium. To this latter class belongs the diphtheria toxin which has been so successfully used in the preparation of diphtheria antitoxin. The practical utility of investigating these intracellular toxins has already become evident in the preparation from the intracellular toxin of the typhoid bacillus of a serum having antitoxic value as regards this toxin. The method employed in obtaining these intracellular toxins consists in mechanically breaking up the bacteria when in the *brittle* condition produced by immersion in liquid air The use of this reagent has the additional advantage of preventing chemical change during the process. In short, the process may be described as producing a *devitalised toxin* while the bacillus is in a condition of *chemical anæsthesia*. The apparatus concerned in this interesting and important research was shown.

Professor F. D. Trouton showed an ingenious arrangement by which the hygrometric state of the air could be gravimetrically recorded directly. When the moisture in the air varies or the temperature changes the weight absorbed by a piece of flannel changes in proportion to the hygrometric state of the air but not to the amount of moisture present. This alteration in weight can be shown by the movement of the arm of a balance from which the flannel is suspended and thus the hygrometric variations may be recorded. [illegible] was demons [illegible] with chlorof [illegible] of calf vacci [illegible] chloroform escapes automatically from the emulsion so that the vaccine is never in contact with a stronger solution of chloroform than 1 in 200. The value of this method has been practically demonstrated. The use of vaccines freed from all extraneous germs and after all the traces of chloroform have been removed has given results for vaccination and revaccination of a very satisfactory kind. By this method vaccine free from extraneous bacteria can be distributed for use, it is stated, within 24 hours of its collection from the calf. This fact is of the utmost importance should the demand for vaccine, as during the occurrence of small-pox epidemics, be very great. Dr. W. J. Russell, exhibited a number of photographs of dust deposits formed upon glass plates which were left at rest for a few minutes at a slightly higher temperature than that of the surrounding atmosphere. The dust took many beautiful patterns chiefly of the double diagonal type Speaking of dust mention should be made of the samples of volcanic dusts exhibited by the West Indies Volcanoes Committee of the Royal Society. There was a very interesting collection of relics and photographs on view illustrating the late eruptions in St. Vincent and Martinique. Mr. S. G. Shattock showed an interesting example of true (glandular) hermaphroditism in a domestic fowl. The comb and wattles of the bird shown were male, while the tail and plumage in general were female. The section showed a left oviduct and two reproductive glands The right lesser gland exhibited testicular tubuli, some of which contained spermatozoa; the left gland contained inactive testicular tubuli and an ovum. Dr. Aldo Castellani exhibited a specimen of trypanosoma found by him in the cerebro-spinal fluid from patients suffering from sleeping sickness in Uganda. In the committee-[illegible] was given of the new incandescent oil [illegible] ity [illegible] on. [illegible] and [illegible] t is [illegible]

Demonstrations were given by means of the electric lantern during the evening by Sir Benjamin Baker who exhibited a series of lantern slides illustrative of the Nile Dam works Professor Harold B. Dixon also used the lantern for projecting on the screen his interesting photographs of explosion flames taken on very rapidly moving films. The genesis of the explosion waves as the flame travelled from the point of ignition and the influence of reflexions from the ends of the tube could readily be seen. Photographs of sound waves moving through the explosion flame were also shown, the movement enabling the approximate temperature of the flame to be calculated.

THE ARMY MEDICAL SERVICES.

WE are authorised to state the following facts for the information of intending candidates for the Royal Army Medical Corps.

The Army Medical Service, under the Royal Warrant of 1902, gives greatly increased advantages to officers of the Royal Army Medical Corps and offers an attractive career to young medical men

The provisions of the new Warrant insure —

1. Sufficient pay to enable the officer to support himself from the date of entering the service. (See Appendix, Schedule of Pay.)
2. Increased rates of pay to officers in charge of hospitals, or when selected for specialist appointments.
3. Opportunities of professional improvement by work in the Royal Army Medical College, by the study of disease in foreign countries and by original research.
4. Advancement on account of professional ability and merit and not only by order of seniority.

5. Permission to retire at the end of three years' service and to join the reserve of the corps, receiving a small annual honorarium. Permission may be given to officers of this reserve to rejoin the corps within a certain period.
6. The certainty of obtaining a gratuity of £1000 on retirement after nine years' service and of obtaining a *pension* of £1 a day on retirement after 20 years' service, with increased rates of pension after longer terms. Pensions at higher rates are paid to officers who retire on account of injuries received when on duty.

Pensions are granted to the widows and children of officers.

THE ENTRANCE EXAMINATION.

A competitive examination for commissions in the Royal Army Medical Corps takes place twice a year, in January and July. The number of vacancies is announced before each examination, and varies from 30 to 40 at each competition. After passing the ordinary physical examination for entrance into the army, and being accepted by the Advisory Board for Army Medical Services, the candidate comes before the Board of Examiners for the entrance examination.

The examination is conducted so as to test the candidates' practical knowledge and experience in general medicine and surgery. It is expected that candidates with a good knowledge of their profession will succeed in passing this test without the necessity for special reading in the earlier subjects of the medical curriculum. The written part of the examination consists of commentaries on cases set by the examiners and of reports on patients examined by the candidates. The *vivâ voce* part of the examination is of a clinical character, and includes the subjects of pathology and surgical anatomy only to the extent required in a general examination on practical medicine and surgery.

The Board of Examiners consists of eight physicians and surgeons appointed from the hospitals and medical schools of the United Kingdom.

On obtaining a place the candidate is gazetted as a lieutenant on probation and passes into the Royal Army Medical College in London where he receives a two months' course of instruction from the professors of the College in hygiene, bacteriology, military surgery, and military medical administration. He resides in the College and has the advantage of associating with other officers of the corps. At the end of this course he is examined in the subjects of hygiene and bacteriology and then proceeds to Aldershot where, at the training school of the Royal Army Medical Corps Depôt, he receives a further course of instruction for a period of three months on the military part of his future duties, such as routine medical duties in military hospitals and barracks, the drills and exercises of the corps, the practical work of field ambulances, military law, &c.

The sum of the marks gained at the entrance examination, the examination at the Royal Army Medical College and at the Aldershot examination, determines his seniority in the Army List. On qualifying at these examinations his commission as Lieutenant in the corps is now confirmed.

The number of marks obtainable in the three examinations is as follows :—

	Maximum marks.
1. The entrance examination by the Board of Examiners	800
2. Examination at the Royal Army Medical College	100
3. Examination at Aldershot	100

APPOINTMENTS IN CIVIL HOSPITALS.

If officers, at the time of entering the corps, hold, or have an immediate prospect of holding, resident appointments at any one of the large general hospitals recognised by the Advisory Board, they may be "seconded" for the space of one year while holding such posts. They have thus the privilege of retaining their places in the Army List and the time of tenure of the appointment is counted as service towards promotion and pension, but they do not receive Army pay.

FOREIGN SERVICE.

On leaving Aldershot the Lieutenant is appointed to a military hospital, and in about a year from the date of joining he will proceed to India or to one of the colonies and will probably be attached to a battalion, regiment, or other unit. This opportunity of proceeding abroad is usually regarded as one of the most pleasant episodes in the medical officer's career. He sees fresh countries and life under new conditions and has the opportunity of securing the confidence of his military charge and of gaining experience in practice. In addition to the experience afforded by the military hospitals under his immediate care there are in India, and in most of the colonies, civil hospitals where facilities for observation are never denied him and where he can study the diseases peculiar to the countries in which he may serve. In the same way as an officer of the Indian Medical Service he is permitted to engage in civil practice, which, in some stations, affords him a considerable increase of income. Such private practice is also permitted in colonial stations.

Until recently there was much well-grounded complaint of the inadequacy of the pay of the British medical officer in India, but with the augmentation sanctioned by recent regulations this ground of complaint no longer exists. The pay of the young officer goes further abroad than it does at home, and in India and elsewhere it is sufficient to enable him to live comfortably and to take part in the sports and amusements of his brother officers.

PROMOTION TO CAPTAIN.

At the end of three and a half years after joining the Royal Army Military College the officer, after passing a practical examination in the military duties of his rank, is promoted to be Captain. On completing his tour of foreign service of three or five years, according to the period of his station, he returns home and during his home service is appointed to the Royal Army Medical College for a course of six months' study. This is largely occupied in attendance on the clinical practice of various London hospitals, under selected clinical teachers in medicine, surgery, and in certain special subjects.

The teachers for the year 1903 are the following :—

Medicine	Dr. Sharkey. Dr. Hale White.
Surgery...	Mr. Pearce Gould. Mr. Stanley Boyd.
Dental Surgery	Mr. Badcock.
Dermatology	Dr. Colcott Fox.
Laryngology...	Mr. Steward.
Midwifery and Gynæcology	Dr. Dakin.
Ophthalmology	Mr. Treacher Collins.
Otology...	Mr Cheatle.
Pædiatrics	Dr. Garrod.
Psychological Medicine ...	Dr. Craig.
Specific Fevers	Dr. Foord Caiger.
Bacteriology.	Major Leishman, R.A.M C., Professor of Pathology, R.A M. College. Assistant Professor, Captain Harvey.
Skiagraphy	Surgeon-General Stevenson, C.B., Professor of Military Surgery, R A M. College.
Advanced Operative Surgery	Surgeon-General Stevenson, C B., Professor of Military Surgery, R A.M. College.
Hygiene	Major R.H Firth, R A.M C., Professor of Hygiene, R A.M. College. Assistant Professor, Captain Fowler, R A.M.C.
Pathology and Tropical Diseases	Major Leishman, R.A.M.C. Captain Harvey, R.A.M.C.

PROMOTION TO MAJOR.

At the end of this course of instruction the Captain is ready for his examination for promotion to the rank of Major. This examination, like the entrance examination, is of as practical a character as possible and includes general medicine and surgery, bacteriology and hygiene, and a special subject chosen by the candidate. This examination forms a very important event in his career in the army. An officer who shows special proficiency at this examination may gain acceleration of promotion to the extent of three months, six months, 12 months, or 18 months, and those who have shown aptitude in the special subjects chosen in their examination may be subsequently selected to hold specialist appointments at various army centres, receiving increased pay at the rate of about £45 per annum.

The officer, after from 10½ to 12 years' service from the date of entering the Royal Army Medical College, and on qualifying at this examination, is promoted to the rank of Major and various important and responsible appointments become open to him After completing a period of home service he proceeds on his second tour of service abroad and will be in all probability posted to a position of responsibility when his pay and allowances will amply meet all his needs

PROMOTION TO LIEUTENANT COLONEL

After the fifteenth year of service the officer proceeds to his last examination, which deals with those purely military subjects, with which he has gradually become familiar during his career This examination is also of a practical character and is intended to ascertain his administrative ability in view of further promotion

After passing this examination the officer becomes eligible for selection to the rank of Lieutenant Colonel Officers of this standing occupy prominent positions in the army, they command the depôt at Aldershot, they form the staff of the Director General, they have the charge of large hospitals and may become entitled to a very considerable increase in pay, amounting in some cases to as much as £180 a year After 20 years total service the officer may retire upon a pension of £1 per diem

PROMOTION TO THE HIGHER GRADE OF LIEUTENANT COLONEL AND COLONEL

Lieutenant Colonels are on selection advanced to a higher rate of pay and from this higher grade of Lieutenant Colonels are selected the Colonels of the corps Colonels are promoted on selection to the rank of Surgeon General and from the Surgeon Generals the Director General is appointed

BREVET PROMOTION FOR DISTINGUISHED SERVICE

Brevet promotion, which implies advancement in army rank as distinguished from regimental rank, as in other branches of the service, is now granted to medical officers for distinguished service in the field and for distinguished service other than in the field, such as distinction in original investigation and research

OFFICERS ELIGIBLE FOR SPECIAL HONOURABLE RECOGNITION

The officers of the Royal Army Medical Corps are eligible for military honours and rewards at the hand of the Sovereign and there are six honorary physicians and six honorary surgeons to the King appointed from among the officers of the Royal Army Medical Corps

It is worthy of notice that a large proportion of Victoria Crosses have been awarded to medical officers for valour

APPENDIX

EXPENSES, SPECIAL ADVANTAGES, PAY

The expenses of all officers have been considerably reduced as the result of recent legislation, by which the Government provides furniture in their quarters at a low rent, gives them a free field service outfit, &c

The medical officer has in common with all other officers of the army, the following advantages—viz , the occupation of Government quarters, or allowance in lieu thereof; military precedence, according to seniority, horse allowance when mounted, the employment of soldiers as servants; honorary membership of messes, &c

In large stations such as Aldershot, Netley, London, Rawal Pindi Lucknow, &c , there are messes of the Royal Army Medical Corps

PAY IN INDIA

	Rupees per mensem
Lieutenants	420
Captains	450
After seven years service	530
ten „ „	650
Majors	789
After 15 years service	826
Lieutenant Colonels	1100
Specially selected	1200
Charge pay from 60 rupees to 240 rupees per mensem according to size of hospital	
Specialist pay	60

Captains and Majors after qualifying in special subjects, if appointed specialists draw 2*s* 6*d* a day (£45 12*s* 6*d* per annum, 60 rupees per mensem in India) in addition to pay

Charge pay up to £180 per annum (240 rupees per mensem in India) according to number of beds is given to officers in charge of military hospitals

The following are examples of the emoluments which may be obtained by medical officers of various ranks —

Captain (say of ten years' total service)—

		£	s	d
Pay and allowances		474	19	11
Specialist pay		45	12	6
Charge pay		45	12	6
		566	4	11

Major (say of 10½ years' total service)—

		£	s	d
Pay and allowances		586	4	3
Specialist pay		45	12	6
Charge pay	from £91 5*s* to	182	10	0
		814	6	9

Lieutenant-Colonel (say of 18½ years' total service)—

		£	s	d
Pay and allowances		713	19	3
Charge pay	from £91 5*s* to	182	10	0
		896	9	3

If commanding depôt Royal Army Medical Corps extra pay of £92 per annum is given

FOREIGN DEPARTMENT.

ANALYSIS OF FOREIGN MEDICAL JOURNALS.

OMODEI'S ANNALI UNIV. DI MEDICINA.

Curious case of a horny excrescence growing from the head.

Paul Rodriquez of Messico, a tall man, and of athletic temperament, was in the habit of wearing a large cap of a peculiar figure, in order to conceal a tumour which projected from the side of his head, and which had at last reached an extraordinary size. Being at work in a warehouse, he was desired one day to assist in lifting a barrel of sugar into a cart; the barrel slipt back a little and struck Rodriquez with such violence on his concealed horns, that he fell upon the pavement insensible. In this state he was conveyed to the hospital of St. Andrew, which afforded the surgeons an opportunity of examining accurately these curious growths. A horny projection was found growing from the right and anterior part of the head, measuring *fourteen inches* in circumference; and about one inch from its base it divided into *three branches*, two large and one small. The central horn which was the largest, was curved and descended many inches below the ear, and then turned forward upon the cheek. The smallest excrescence of the three was situated just in front of the large one, and passed down on the cheek, just behind the external angle of the eye, as far as the middle of the superior maxillary bone, and was about three inches in length. Its extremity was separated about an inch from the curved termination of the middle horn, so that a considerable portion of the cheek, of a semicircular figure, was left between these two excrescences. The middle excrescence was very much the shape of a ram's horn, and had circular depressions and elevations marking the progress of its growth, just as the rings are seen on the horns of the ram, and it exhaled an odour exactly like the horn of that animal.

The violence with which the blow had been inflicted had broken off the lower extremity of the posterior horn, and had smashed its structure still higher up, so that its cavity was filled with blood. This singular excrescence did not adhere to the bones of the head, but appeared to grow from a cyst in the scalp, the sides of which were very thick, and lined with a smooth membrane.

Many analogous cases are on record, but we have never met with any account of a case in which the size of the horny excrescence was so large as in the present.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Sanitary Circumstances of the Ashington Urban District and on Recent Enteric Fever therein, by Dr. L. W. DARRA MAIR.[1]—Ashington urban district comprises two Northumberland colliery villages, Hirst and Ashington, with populations respectively of about 7600 and 6300. Both villages are inhabited mainly by miners who work at one or other of three collieries belonging to the Ashington Colliery Company. Hirst is the newer place of the two and its residents are for the most part young adults with their families, whereas Ashington contains an older generation of miners. Dr. Darra Mair gives an account of the sanitary conditions of both villages, with particular reference to the opportunities for the spread of enteric fever. He draws attention to the way in which new dwellings are being put up without any regulation by building by-laws, to the uneven and unpaved surfaces at the backs of the houses, and to defective arrangements for emptying the ashpits and privies which lead to fouling of the soil. This is the more important as these receptacles are emptied more frequently and systematically than is the case in many villages of a like character, the colliery company undertaking to remove refuse once a fortnight. The company also supplies water to both villages. There is a service of mains for "slop water" which consists of a portion of the water pumped up in the ordinary operations of the collieries and is used for watering streets, for flushing sewers, and for fire-brigade purposes. Another series of mains supplies Ashington and Hirst with water for drinking and domestic use, which is pumped from certain deep coal mines which are no longer worked. The water from these mines is derived from the sandstone and collects in underground reservoirs formed by the worked-out coal seams. It is pumped to the surface, passed through a filter, and stored in disused boilers which serve as storage tanks. The urban district had for some years past shown a high attack-rate and also a high death-rate from enteric fever. In 1901 187 cases of this disease were notified, 135 occurring in Hirst and 52 in Ashington. 20 of the cases at Hirst and eight of the cases at Ashington were fatal. This outbreak began at the end of August, 1901, and reached its height in October and November. Cases continued to occur in the early months of 1902, the prevalence of the disease ceasing in May. Dr. Darra Mair's inquiries were made in February, 1902, and also later in the year, when he was assisted by Mr. Law of the engineering department of the Local Goverment Board in an investigation of the conditions of the water service. This additional inquiry had become necessary in consideration of the various facts ascertained regarding the outbreak in the autumn of 1901. The dwellings in which enteric fever occurred during this period were scattered throughout both villages, with the exception of the one portion of Hirst which was not supplied with drinking water from the colliery company's mains. The disease occurred with greatest intensity in portions of two parallel streets in Hirst, in which 27 out of a total of 52 houses were affected. These two portions of streets were served by a common water main situated at the termination of the colliery company's water system and forming a "dead end." These and other considerations set out in detail in the report led Dr. Darra Mair to conclude that somehow or other the whole drinking water-supply had become specifically contaminated and had been accompanied by special infectivity of water drawn from taps near the terminals of the mains. This seemed to be the more probable as he was able to exclude any idea that milk or other articles of food had been concerned in producing the outbreak in consequence of careful local inquiries which had been made by Dr. J. M. Hembrough, medical officer of health of Northumberland. When, however, search was made for possible sources of contamination of the underground reservoirs of the colliery company the results proved to be almost entirely negative. No opportunity of leakage from portions of the collieries where work is going on could be detected. Obviously, however, a number of intricate geological questions would need to be dealt with before the absence of such opportunities could be asserted and it is noteworthy that analysis of three samples of the colliery company's drinking water-supply, taken from taps in Hirst and Ashington on the same day, varied greatly in respect of total solids and free and albuminoid ammonia. This points either to unrecognised opportunities of con- [illegible] possibilities of [illegible] Dr. Darra Mair [illegible] ne which must remain under suspicion, even after the thorough overhaul of the system of distributing pipes which he advocates. No alternative source of supply is readily available for the Ashington district alone, but possibly a solution of the difficulty may be found in combination with neighbouring districts for water-supply purposes on the lines of certain schemes now under the consideration of the Northumberland County Council.

[1] London: Eyre and Spottiswoode, East Harding-street; Edinburgh: Oliver and Boyd; Dublin: E. Ponsonby. Price 4d.

On the General Sanitary Circumstances of the Parish of Loose in the Rural District of Maidstone, with especial reference to Drainage and Excrement Disposal, by Dr. R. D. SWEETING.—Dr. Sweeting reports the results of an inquiry ordered by the Local Government Board into an application by the Maidstone rural district council for the issue of an order declaring the cost of scavenging cesspools to be "special expenses," in the sense of the Public Health Acts, upon the whole or upon part of the parish of Loose on the outskirts of Maidstone. The matter had become pressing owing to the need of some system to supersede the present objectionable arrangements by which slop-water, excrement, and various kinds of refuse are habitually discharged into the tributary of the Medway which passes through Loose. The district council considered the provision of sewers to be impracticable in view of the local opposition made to the proposal and hence it advocated the general provision of cesspools in that portion of the parish which at present sends its liquid refuse into the stream, together with a system of periodical cleansing of these cesspools by the council at the cost of the parishioners concerned. Dr. Sweeting describes the condition of affairs in detail and makes a series of suggestions for remedying the present objectionable conditions without having recourse to a cesspool system. He recommends also that "special expenses" in respect of scavenging existing cesspools, as well as of providing and maintaining sewers, should be chargeable to the parish as a whole.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Exeter Urban District.—The number of cases of enteric fever notified in Exeter during 1902 was, Dr. John Woodman reports, the lowest on record and he is inclined to attribute the diminution to the fact that within recent years the sewage of Exmouth has been directed from the cockle beds near to which it formerly discharged. It would have been useful had further details as regards the age distribution of the cases in the several years been given since, so far as we remember, the outbreak which occurred in Exeter as the result of the consumption of cockles at Exmouth was confined mainly to children at school ages. As a matter of fact the total cases (33) are only five lower than those (38) notified in 1895. But be this as it may, no one will question the propriety of Dr. Woodman's advice that the discharge of sewage in the immediate vicinity of any shell-fish beds should be prohibited. Dr. Woodman accentuates the importance of protecting the breeding grounds of shell-fish, but, as a matter of fact, the breeding grounds are second in importance to the "fattening" or market grounds—i.e., those places from which shell-fish are taken for immediate consumption. Pulmonary tuberculosis is notifiable in a voluntary sense in Exeter but Dr. Woodman regards this form of notification as of little value. He thinks that disinfection should be compulsory in all premises in which deaths from pulmonary tuberculosis have occurred. The public analyst of the city reports that in the public water-supply the number of micro-organisms per cubic centimetre in three samples examined was 35, 93, and 120, but it would have been interesting had the nature of such organisms been stated and had the filtrate from each of the filter beds been dealt with separately.

Knutsford, Middlewich, Winsford, and Biddulph Urban Districts.—Mr. T. W. H. Garstang reports that the offer of the several district councils referred to above to pay 2*s.* 6*d.* for each case of pulmonary tuberculosis notified has not met with much support from the medical practitioners concerned as only 10 such cases were notified during 1902, the deaths during the same period having been 33.

Plympton St. Mary Rural District.—This district council has decided to contribute to the part maintenance of one bed at the Didworthy sanatorium for consumption. In connexion with this subject of tuberculosis Mr. S. Noy Scott makes some very pertinent remarks. He thinks it well "to issue a word of warning with regard to the great expectations which are at present being raised as to sanatoria. It must not be forgotten that sanatoria of phthisis are to be mainly regarded as hospitals for dealing with the results of tuberculosis and for curing or arresting disease and should therefore hardly be classed amongst such [illegible] as subsoil drainage, w[illegible] and air, prevention o[illegible] unhealthy occupations less dangerous to the workers, and, therefore, although there can be no question as to the usefulness of sanatoria in the treatment of phthisis, yet it may be safely said that a given sum of money used in the promotion of the above list of 'primary preventive measures' would do more towards the permanent reduction of the death-rate from phthisis than many times the same sum expended in the building and support of sanatoria."

Wimbledon Urban District.—Measles has been notifiable in this district for the last five years and as a result of the experienced gained Mr. E. Pocklington, the medical officer of health, does not advise the continuance of the measure. The main arguments used seem to be that this measure has not prevented epidemics nor has it reduced the mortality from the disease. Mr. Pocklington is unable, he states, to stay the spread of the disease in schools inasmuch as the schools have not been closed when he regarded it as necessary. This statement appears to need some amplification. It is also urged that "were it possible by notification, &c., to check the spread for a few years we should have on our hands a large number of liable children to whom an epidemic would spread very rapidly when it eventually did occur, as surely would be the case." This is a somewhat fatalistic view to take of the situation and it overlooks the fact that there are obvious advantages in postponing an attack of measles. Although we fully admit that the subject of the notification of measles is a very difficult one we cannot regard the arguments here adduced for a discontinuance of notification as very convincing. Mr. Pocklington states that danger lies not in measles when the disease is properly looked after but in those cases which are neglected on account of their triviality. But surely one result of notification should be the education of the poorer classes in the proper care of measles

Brighton Urban District.—In the middle of 1902 Brighton had a population of 124,539 and in his current annual report Dr. Arthur Newsholme furnishes the 1901 census figures for [illegible] neighbourhood. The birth-rate in Brighton [illegible] Dr. Newsholme refers [illegible] the general reduction in the birth-rate in the country as a whole. He ascribes this reduction almost solely to the prevention of conception by artificial means. He thinks there is not "the slightest reason for believing that the potential fecundity of civilised man is declining." There are, however, many who would regard this statement as hardly supported by what is known as to the behaviour of animals under domestication. In connexion with small-pox Dr. Newsholme supplies some facts which tend to show the advantage of the notification of chicken-pox and this disease is consequently to be notifiable for another year in Brighton. With regard to both scarlet fever and diphtheria some interesting illustrations are given in the report before us of the importance of the early recognition of cases of these diseases and of the evil consequences which ensue from overlooking cases in their initial stages. Certainly the more we learn of epidemic diseases the more importance do we attach to the influence of unrecognised cases. Prophylactic doses of antitoxin were given in 27 instances during 1902, the medical practitioners receiving a fee of 2*s.* 6*d.* for each case. None of the persons thus treated contracted the disease. As regards the value of this treatment Dr. Newsholme raises questions as to whether the employment of antitoxin in this prophylactic sense, although it may in some cases prevent the disease from developing, may not prevent the person so treated from becoming a source of infection. In the matter of the bacteriological examination for suspected diphtheria we are glad to see that in Brighton "three consecutive failures to find the diphtheria bacillus are required before any importance can be attached to negative results." There were 42 cases of enteric fever in Brighton during 1902 and Dr. Newsholme states definitely that of this number "11 were caused by oysters, six and three secondary to these were caused by mussels, and one was caused by whelks, with one case secondary (by personal infection)." With regard to the evidence as to the connexion between shell-fish and diseases the statement is made that "it is purely circumstantial and can only be regarded as conclusive by those who, like myself, have felt the steadily increasing weight of conviction produced by the steady flow of cases for which no cause can, after diligent search, be detected other than the previous consumption of shell-fish." The words "of shell-fish known to have been derived from sources liable to specific pollution" are perhaps necessary to complete this sentence, as if the oysters were derived from mid-ocean and had no opportunities of becoming polluted the mere fact of the consumption of oysters would be of little greater value than the fact of the consumption of any other article of food theoretically capable of conveying enteric fever. But apparently Dr. Newsholme could, at least in some of the cases, have quite well added the words which we suggest, although we fear that the statements of some oyster merchants as regards the source of their shell-fish are not always to be relied upon. But in any circumstances there can be no question whatever that the sale of shell-fish from polluted sources should be prohibited, and we are glad to see that Brighton has recently drafted a by-law which aims at "prohibiting the sale or exposure for sale in Brighton fish market of oysters or other shell-fish known to have come from a sewage-contaminated source." The words used in the by-law of "polluted or contaminated with sewage" might perhaps be held by some bacteriologists to apply to almost every estuary in England as well as to much of the littoral, but Dr. Newsholme may be trusted to take a reasonable view of the situation and to content himself with excluding shell-fish concerning which there can be no reasonable doubts. We much hope that Brighton will obtain, either in the shape of a modified by-law or otherwise, the protection which it seeks against the consumption of specifically polluted shell-fish. The voluntary notification of pulmonary tuberculosis has now been in operation in Brighton since 1899 and there appears to be a steady increase in the number of cases notified year by year. Certain cases seem to have been notified several times. In case of death or in the event of change of address disinfection and cleansing of the invaded houses are undertaken by the town council. As the result of four years' experience of the notification of pulmonary tuberculosis in Brighton Dr. Newsholme is of opinion that the measure is necessary in the interests of the public health. He is "more convinced than ever that the effective prevention of the spread of infection can only be secured when the family practitioner and the medical officer of health coöperate." Arrangements have now been made for the admission of cases of pulmonary tuberculosis into the isolation pavilion of the borough sanatorium, one of the main objects of this step being to educate the patients in precautionary measures.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8911 births and 4441 deaths were registered during the week ending May 16th. The annual rate of mortality in these towns, which had been 17·4, 17·5, and 15 9 per 1000 in the three preceding weeks, further declined to 15·4 per 1000 last week. In London the death-rate was 14·4 per 1000, while it averaged 15·8 in the 75 other large towns. The lowest death-rates in these towns were 3·3 in Hornsey, 7·1 in East Ham and in Hastings, 7·9 in Warrington, 8·6 in Willesden, 9·1 in Ipswich and in Handsworth, 9·8 in Kings Norton, and 10 6 in Devonport; while the highest rates were 21·2 in West Bromwich, 21·4 in Oldham, 21·8 in Merthyr Tydfil, 22·2 in Coventry, 22·9 in Stockport, 23·1 in Hanley, 24·0 in Rochdale, and 24·1 in Middlesbrough. The 4441 deaths in these towns last week included 428 which were referred to the principal infectious diseases, against 504, 518, and 457 in the three preceding weeks; of these 428 deaths 125 were referred to measles, 110 to whooping-cough, 57 to diarrhœa, 52 to diphtheria, 41 to scarlet fever, 26 to "fever" (principally enteric), and 17 to small-pox. In Hornsey, Brighton, Norwich, Stockport, Huddersfield, Halifax, York, South Shields, and in eight other smaller towns, no death from any of the principal infectious diseases was registered last week, while they caused the highest death-rates in Tottenham, Wolverhampton, Nottingham, Bootle, Wigan, Oldham, Merthyr Tydfil, and Swansea. The greatest proportional mortality from measles occurred in Croydon, Tottenham, Coventry, Nottingham, Wigan, Bolton, Manchester, and Swansea; from diphtheria in Hanley, Oldham, and Merthyr Tydfil; from whooping-cough in Salford, Oldham, Barrow-in-Furness, Sheffield, and Merthyr Tydfil; from "fever" in Wolverhampton; and from diarrhœa in Wolverhampton and West Bromwich. Six fatal cases of small-pox were registered in Liverpool, two in Leeds, and one each in Aston Manor, Bootle, Manchester, Oldham, Rochdale, Burnley, Bradford, Hull, and Gateshead, but not one in any other of the 76 large towns. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had risen from seven to 60 on the eight preceding Saturdays, were again 60 on Saturday, May 16th; seven new cases were admitted during the week, against nine, 12, and 17 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1756, against 1700, 1717, and 1730 at the end of the three preceding weeks; 236 new cases were admitted during the week, against 243, 235, and 229 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 280, 284, and 260 in the three preceding weeks, declined again last week to 226 and were five below the number in the corresponding period of last year. The causes of 67, or 1·5 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Plymouth, Bristol, Bolton, Salford, Oldham, Newcastle-on-Tyne, and in 36 other smaller towns; the largest proportions of uncertified deaths were registered in Leyton, Liverpool, Bootle, St. Helens, Preston, Sheffield, Rotherham, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·5, 19·2, and 17·9 per 1000 in the three preceding weeks, rose again to 18 0 per 1000 during the week ending May 16th, and was 2·6 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 7·7 in Perth and 12·9 in Aberdeen to 19 3 in Glasgow and 22·5 in Greenock The 590 deaths in these towns included 25 which were referred to whooping-cough, 16 to measles, 12 to diarrhœa, six to diphtheria, five to "fever," and four to scarlet fever, but not one to small-pox. In all, 68 deaths resulted from these principal infectious diseases last week, against 57 in each of the two preceding weeks. These 68 deaths were equal to an annual rate of 2·1 per 1000, which was 0·6 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 30, 32, and 26 in the three preceding weeks, further declined last week to 25, of which 12 occurred in Glasgow, seven in Edinburgh, and four in Greenock. The deaths from measles, which had been four, seven, and eight in the three preceding weeks, further rose to 16 last week, and included nine in Glasgow, and five in Edinburgh. The fatal cases of diarrhœa, which had been 11 in each of the two preceding weeks, increased last week to 12, of which seven were registered in Glasgow, two in Dundee, and two in Aberdeen. The deaths from diphtheria, which had been two, one, and five in the three preceding weeks, further rose to six last week and included four in Glasgow, where also two of the five deaths from "fever" were recorded. The fatal cases of scarlet fever, which had been four in each of the two preceding weeks, were again four last week, and included two in Edinburgh and two in Paisley. The deaths referred to diseases of the respiratory organs in these towns, which had been 129, 125 and 104 in the three preceding weeks, further declined last week to 101, and were 13 below the number in the corresponding period of last year. The causes of 24, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·8, 25·7, and 25·3 per 1000 in the three preceding weeks, further declined to 22·3 per 1000 during the week ending May 16th. During the past four weeks the death-rate has averaged 24·5 per 1000, the rates during the same period being 16·1 in London and 17·2 in Edinburgh. The 162 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 22 from the number in the preceding week and included 15 which were referred to the principal infectious diseases, against eight, nine, and 15 in the three preceding weeks; of these, five resulted from measles, four from small-pox, three from whooping-cough, and one each from scarlet fever, from "fever," and from diarrhœa, but not one from diphtheria. These 15 deaths were equal to an annual rate of 2·1 per 1000, the death-rates last week from the same diseases being 1·5 in London and 2·5 in Edinburgh. The deaths from measles, which had been one, one, and 0 in the three preceding weeks, increased last week to five. The fatal cases of small-pox, which had been one, three, and four in the three preceding weeks, were again four last week. The deaths from whooping-cough, which had been one, one, and four in the three preceding weeks, declined again last week to three. The 162 deaths in Dublin last week included 34 of children under one year of age and 48 of persons aged 60 years and upwards; the deaths among both infants and elderly persons slightly exceeded the respective numbers recorded in the preceding week. Two inquest cases were registered, and 71, or nearly 44 per cent., of the deaths occurred in public institutions. The causes of five, or more than 3 per cent., of the deaths in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: F. F. Lobb to Royal Marines Division, Plymouth, and E. F. Mortimer to Plymouth Hospital.

Civil Practitioner: T. Foley to be Surgeon and Agent at Ardmore, Ballymacart, and Whiting Bay.

1ST LIFE GUARDS.

Surgeon-Major B. W. C. Deeble to be Surgeon-Lieutenant-Colonel. Dated Feb. 3rd, 1903.

ROYAL ARMY MEDICAL CORPS.

Major J. Paterson, from half-pay, to be Major, vice V. E. Hunter, deceased, with precedence next below A. P. Blenkinson. Dated April 26th, 1903. Lieutenant G. W. G. Hughes, from the seconded list, to be Lieutenant. Dated May 2nd, 1903. Lieutenant-Colonel William Birkmyre Miller, retires on retired pay. Dated May 16th, 1903.

The undermentioned Lieutenants to be Captains (dated April 25th, 1903):—T. Biggam, W. L. Baker, F. W. Cotton, F. M. Parry, B. R. Dinnis, W. J. P. Adye-Curran, J. Powell, R. L. Argles, J. G. Foster, E. G. Ford, F. S. Walker, L. M. Purser, W. Bennett, P. G. Stock, H. B. Fawcus, T. E. Fielding, E. P. Sewell, C. H. Straton, B. S Bartlett, R. T. Brown, G. Carroll, D. O. Hyde, A. E. Hamerton, G. J. Houghton, J. G. Churton, A. D. Waring, T. H. Stevenson, J. M. Cuthbert, F. McLennan, A. F. Weston, J. Dorgan, O. H. Furnivall, J. H. Robinson, and Fitz G. FitzGerald.

THE ROYAL MILITARY TOURNAMENT.

Important as are the many aspects from which the Royal Military Tournament at the Agricultural Hall may be viewed there is one which should be placed before all others—namely, the point of view of charity. The entire profits derived from the performances—an aggregate of £47,000 for the past seven years—are devoted by the commander-in-chief to naval and military charities, and for this reason alone the tournament should receive the widest support. But the tournament has an important bearing on the education of the general public in military matters and forms a means of healthy amusement for the people, to say nothing of its use as an aid to recruiting. For the present we must confine ourselves to a brief reference to the displays and competitions, reserving for another occasion, if space permits, a more critical review of the tournament. From a spectacular point of view the pageant, which is a miniature representation of the Delhi durbar, is enthusiastically appreciated, as is also the military tattoo by massed bands; the latter item, however, is only to be seen and heard three times in the fortnight during which the tournament is in process. It is worth a visit to the Agricultural Hall to see either of these items alone, but there are other "turns"—if we may borrow a word from music-hall parlance—which are equally attractive, and amongst them we may mention the musical double ride by the 2nd Life Guards, the finest performance of this description which has ever been seen at the tournament. Next week the Life Guards will give place to the 5th Royal Irish Lancers. The displays by the seamen of the *Excellent* and by the Royal Marines are referred to in another part of our present issue (p. 1457). Then there are the competition of the Army Service Corps, a wonderful exhibition of smartness; the musical drive by the Royal Artillery; bareback riding, furnished by a team from the Cavalry Depôt at Canterbury; the display by the A Battery of the Royal Field Artillery; wrestling on horseback and the usual competitions, which include tent-pegging, lemon-cutting, heads and posts, and the combats between men using the various arms of the service. Altogether the twenty-fourth Royal Military Tournament is the best which has ever been held at Islington and Major-General Oliphant and his committee deserve the best thanks of the public for providing such an excellent, instructive, and entertaining programme. The medical and sanitary arrangements, though perhaps not all that could be desired, are undoubtedly the best that can be obtained in a building which does not belong to the military authorities and which is certainly not adapted to military performances. Surgeon-Lieutenant-Colonel W. R. Crooke-Lawless of the Coldstream Guards is the principal medical officer and he is assisted by Captain F. A. Symons, R.A.M.C. Lieutenant-Colonel A. R. Rowe is in charge of the veterinary arrangements. The tournament will close on May 30th.

THE WOUNDED IN NAVAL WARFARE.

The disposal of the wounded in naval warfare is confessedly a very difficult problem. In a lecture delivered recently at the Royal United Service Institution and published in our present issue (p. 1431) Dr. Philip N. Randall, late R.N., advocated the plan which has seemed to be the most plausible to those who have given the matter consideration, namely, the provision of vessels flying the Geneva Cross and specially fitted out for the purpose. These should be attached to a fleet and utilised for the reception and treatment of the wounded during or immediately after an engagement. There seemed to be a consensus of opinion among those who took part in the discussion that it would prove unsafe and impracticable to attempt any removal of the wounded during an action and that beyond having first aid rendered to them the wounded must remain where they were until the action was over and their safe removal could be assured.

THE ARMY CORPS.

Whether an army corps scheme borrowed from the continent or an organisation by divisions be best suited to this country from a strategical point of view is a matter into which we need not enter. It must be admitted, however, that the War Office return just issued giving the actual numbers and peace establishment of the units in the First, *Second*, *Third*, and *Fourth Army Corps* goes a long way in showing that such corps are not a mere paper organisation, and that they are not, as has been alleged, only phantom corps, but that they have a fairly real existence and that Mr. Brodrick's contentions regarding his new scheme have been so far justified.

The King has granted to Captain Henry Nason Dunn, R.A.M.C., His Majesty's Royal licence and authority that he may accept and wear the Insignia of the Fourth Class of the Imperial Ottoman Order of the Osmanieh, conferred upon him by His Highness the K[illegible] of valuable services rendered to [illegible]

The report of the committe[illegible] existing conditions under which canteens and regimental institutes are conducted, together with a minority report and appendices, has been issued as a Parliamentary Blue-book.

and found that the child, a six and a half months' one, had been born two hours, but that the placenta was still undelivered. This latter was expelled without any difficulty, but on finding the uterus still flaccid I asked for the ergotine. To my astonishment I discovered that a neighbour in attendance had mistaken the husband's instructions "to give two of these at once" and had instead given the tube itself and wondered where another one was. The patient had taken it in good faith, thinking it a new form of drug and wondering only why it was so long. Of course there was nothing to do but to wait. Castor oil was given freely and on the afternoon of May 5th—four days later—the tube arrived, without any pain and with the cork still *in situ*. I may add that the tube was half full of ergotine, so that the many risks of a foreign body in the intestine were much augmented by the fact of that body containing a poison. The patient is very well now and able to laugh over her adventure.—I am, Sirs, yours faithfully,

W. HERBERT GREGORY, M.D. Edin.

Beverley, May 16th, 1903.

ASPECTS OF LIFE ASSURANCE.

To the Editors of THE LANCET.

SIRS,—With reference to a leading article which appeared in THE LANCET of May 9th, p. 1313, calling attention to the provision which may be made for the future by those who insure their lives, I observe that considerable stress is laid upon the certainty attending this form of investment. Indeed, the fact that a sure provision is made for the survivors of the assured, owing to the financial soundness of life assurance companies, is one always dwelt upon by those who recommend them. Is not, however, this certainty of provision considerably lessened by the fact that many or most life assurance societies issue policies which are in express terms made void by the suicide of the assured? It is, of course, contemplated by them that a man might insure his life at a high figure, pay a premium or two, and then kill himself in order to pay his debts or to provide for his wife and family. I am, I believe, right in saying that suicide is thus excepted in the conditions usually made. If I am wrong you will, no doubt, correct me. My point is that suicide is very frequently the result of what is substantially disease and as much a cause or form of death to which all are liable as typhoid fever or a railway accident. Speaking from my own limited experience I can recall, among others, three persons in particular with whom I was personally acquainted who committed suicide. Two were lawyers with moderate professional incomes and private means; the third was engaged in commerce and his assets at his death amounted to not far from £100,000. Of the two former, one became depressed, I do not know why, and before anyone recognised the fact that his brain was affected took his own life; and the other, as everyone knew, after a severe attack of influenza found himself less able to work than before, got worried, and shot himself. Each of these was precisely the sort of man who might well have insured his life. There was nothing to distinguish him in health from his fellow men; each had a family and was earning enough to have been able to have done so. At all events neither was in embarrassed financial circumstances, any more than the third, whose brain, I believe, was affected by a succession of hunting accidents. I think, however, that I am right in saying that the majority of policies which would have held good had these men died from pneumonia or in the hunting-field would have been rendered void by suicide for which influenza or a hunting accident was directly responsible. Can life assurance, if it is ineffective in case of a death which (as I contend) is as much beyond the power of the assured to avoid as any resulting directly from disease, be regarded as a certain and safe provision for a professional man to make?

I am, Sirs, yours faithfully,

May 18th, 1903. N. M. R.

PRESENTATION TO A MEDICAL PRACTITIONER.—At Crediton (Devon) on May 9th Mr. Leslie Powne, M.R.C.S. Eng., L.S.A., was presented with a pair of gold cuff-links by the members of the ladies' class of the St. John Ambulance Association, in appreciation of his services as honorary lecturer.

THE SECOND INTERNATIONAL CONGRESS OF THE MEDICAL PRESS.

(FROM OUR SPECIAL CORRESPONDENT.)

THE OPENING CEREMONY.

Madrid, May 6th.

IT seems a long way now to hark back to April 20th when the International Congress of the Medical Press held its inaugural sitting in the great hall of the Central University buildings of Madrid. But this congress, instead of terminating its labours on April 22nd, continued its work up to the very last minute on April 23rd, giving its members only just time to rush from the closing sitting of the one congress to assist at the opening ceremony of the other. This latter Congress, the Fourteenth International Congress of Medicine, affording greater general interest than the more specialised questions that concern medical journalism as a profession, it seemed to be better to describe the more important congress first in spite of the fact that it was held last. The inauguration of the Medical Press Congress was a ceremony well worthy of the occasion. Señor Allende Salazar, Minister of Public Instruction, presided, sitting by the side of Dr. Cortezo, the President of the International Congress of the Medical Press, and Dr. Calleja, President of the International Medical Congress. At the presidential table France was represented by Professor Cornil of *Paris*, president of the International Association of the Medical Press, and England by Dr. Frank Pope of Leicester, delegate of the Association of the British Medical Press. The rectors of the Universities of Madrid and of Barcelona were also in the place of honour at the presidential table. Dr. Larra y Cerezo, as general secretary of the Congress, was first called upon to make a statement and to explain the position of affairs. As a medical journalist Dr. Larra cannot be accused of being wanting in enterprise. He had barely terminated his studies, devoting himself especially to questions of hygiene and therapeutics, when he founded, in 1882, the *Therapeutical Review*, and not content with this he even published a daily medical paper called the *Diario Medico*. This was the fruit of youthful enterprise. Dr. Larra was only 23 years old at the time, nevertheless his daily paper lived ten months, and his review still exists though it was merged into *La Medicina Militaire Española* in 1895. Dr.

Dr. Carlos M. Cortezo, President of the International Congress of the Medical Press.

Larra, whose portrait was recently published in these columns,[1] has done much to promote the love of physical exercise in the schools of Spain and is a corresponding member of the British Sanitary Institute. He is likewise the publisher of a Spanish technical medical dictionary, to which a small supplement is issued every year containing the new terms that have arisen during the year.

Dr. LARRA explained that the Congress was attended by representatives of the medical press of the Argentine Republic, Belgium, Cuba, France, Germany, Great Britain, Greece, Holland, Italy, Norway, the United States, and Spain. It was for him a great honour to have assisted in bringing together the thinkers and writers of so many nations.

Dr. CORTEZO, as president of the Spanish Committee of Organisation and of the Congress, now rose to welcome the members and delegates, wishing them to consider themselves at home in Spain. The science which they advocated and taught did not recognise the fictitious differences and antagonisms created between nations. They rose above the frontier lines and in this Congress were all merely members of the same family. To be better understood, Dr. Cortezo spoke in French, German, and Italian as well as in Spanish. He pointed to the libraries that contained works from authors of all these countries. He alluded to the noble initiatives so often taken by France, even at the cost of the lives of her children, to the German profundity of thought and investigation, to the British love of freedom, and to the similar blue sky, history, and race that united Italians and Spaniards.

The MINISTER of PUBLIC INSTRUCTION next rose to speak, and in the name of the King and the Government welcomed the members of the Congress He alluded to the help given by the medical press in connexion with those great discoveries which had revolutionised the practice of surgery. Further the medical press helped to weld together men of science from all parts of the world into one great brotherhood. In the name of the King and of the Government, in the name of the entire Spanish people, he saluted all the delegates, especially those who from distant countries had honoured Spain by their presence, and declared that they were heartily welcome.

Dr. Rafael Ulecia, Delegate of Spain to the Monaco Medical Press Conference.

Professor CORNIL then spoke on behalf of the French medical journalists and expressed his gratitude to the King and the Government for their hospitality and for having rendered the meeting of the Congress possible. He recalled the origin of the International Association of the Medical Press, how it had been talked about at Rome, neglected at Moscow, and, how, with the active aid of the German and French medical press associations, a congress had actually been held in Paris in 1900. The medical press, he maintained, governed the medical profession just as other forms of human activity were governed by their respective journals Virchow, Pasteur, Brown-Séquard, all had their "annals" or "archives." But they had now the medical journal, which like other journals, gave the latest professional news and treated all allied interests. The object of these journals was to preserve men from all that was unwholesome, to relieve and to cure mankind in the accomplishment of its mission. For this end medical journals had proclaimed that humanity had a right to pure air and water and that these were as important as daily bread. So the medical press while confined to its special task was yet helping all other sections of the community. Professor Cornil then alluded to the conference held last year at Monaco where the international committee was treated to th [illegible] lt of the work there [illegible] had been drawn up a [illegible] o the Madrid Congress [illegible] the memory of the late Dr. Laborde, who had so largely helped in drawing up a constitution for the Association, Professor Cornil concluded by pointing out that such congresses helped to refine and to elevate our thoughts.

Dr. POSNER (Berlin) spoke on behalf of the German medical press and that of the German-speaking part of Austria. He alluded to the great work of Virchow as a publicist and said that they would endeavour to follow in his footsteps and he hoped that the progress of science thus promoted would help to bring about international confraternity.

Dr. DEJACE spoke [illegible] —that little country [illegible]

Dr. SANTOS FERN[illegible] striven to keep a medical press alive in that island, in spite of all the troubles and struggles which had afflicted his people. He expressed his gratitude to Spain for the help which it was giving in this great work of scientific progress.

Dr. CRYER (Philadelphia) said a few words on behalf of the medical press of the United States which had taken special pains to obtain full information concerning the congresses to meet in Madrid.

Dr. BLONDEL, (as [illegible] Association of the [illegible] e by the late Dr. Lab [illegible] o witness the crownin[illegible] self so much trouble to raise [illegible]

It was now the turn of England and Mr. ADOLPHE SMITH rose to speak on behalf of the Association of the British Medical Press. He spoke in French and after expressing his gratitude for the royal patronage and the cordiality of the reception given, added that he had been three times in Spain. On the first occasion the country was devastated by a most terrible and widespread cholera epidemic, complicated by numerous earthquakes. On the second occasion war had just broken out with the United States. On the third and present occasion the country was in the throes and distracting cares of a general election. Nevertheless, and in spite of these trying and disturbing circumstances, the people and the Governments of Spain had invariably and with unruffled courtesy assisted him in the performance of his duty as a journalist and as an investigator on behalf of the scientific press.

Dr. ASCOLI having said a few words on behalf of Italy, the MINISTER of PUBLIC INSTRUCTION rose to reply. After expressing his satisfaction at what had been said by various delegates and thanking Professor Cornil for his cordial words, the Minister turned and addressing Mr. Adolphe Smith by name said he could assure him that notwithstanding all the vicissitudes through which Spain had passed and might still have to face the Spanish Government was always alive to the importance, indeed, was perfectly aware, of the great part played by the medical press in the cause of humanity. It was the means of diffusing knowledge to the remotest corners of the world. Medical men were, by the very nature of their duties, often called upon to live in distant parts, in rural districts and other places where it would be impossible for them to follow, and to keep abreast with modern progress but for the fact that it was brought to their doors by the medical press. Therefore he could promise the British representatives that the Government would afford the press every facility to accomplish its high mission, particularly as it was so worthily represented. He was grateful, from the very depths of his heart, to those gentlemen who had come from such great distances to coöperate in the Congress and to awaken the spirit of progress. It was for the medical press to record and to make known all the progress that science achieved. In the name of His Majesty Don Alfonso XIII. he declared that the Second International Congress of the Medical Press was now open.

---

[1] THE LANCET, May 2nd, p. 1270.

The military band then played the Royal March and this concluded the opening ceremony.

THE FIRST DAY.

Madrid, May 7th.

On the morning of April 21st the Congress held its first business meeting, having been duly inaugurated on the previous afternoon. Those members of the international committee who were present met in a private room to arrange the order of procedure. It was generally felt that those who had reports to read and speeches to make on general topics should be heard first and that then the more serious work of coming to a definite agreement and accepting the rules drawn up at Monaco would be more easily accomplished. It was no slight matter to select a judicious course, for there were present a large number of Spanish journalists who, it was quite evident, knew little of the real purpose for which we had met but were nevertheless anxious to deliver speeches or to read papers on what they imagined was, or should be, our motive. To let them disregard the rules of the association so carefully drawn up at Monaco and about which so many present knew little or nothing would be a dangerous proceeding. Therefore the field was thrown open to the readers of papers and the first to speak was Dr. ESPINA DE CAPO. He had a great deal to say about tuberculosis and what the medical press could do to prevent its spread, thus confusing the question of organising the medical press with the question of what medical journals could do to spread knowledge on certain subjects. Dr. SANTOS FERNANDEZ of Cuba described the anti-tuberculosis league of Havana of which he was president. Then came Dr. TOLOSA-LATOUR, member of the Madrid Royal Academy of Medicine, who very sensibly urged that it was the mission of the press in general, of the daily popular political papers, to spread some knowledge of those sanitary measures which were the best preventive of tuberculosis. Dr. AVILEZ having said something about the control of mineral waters in Spain and Professor MARTINEZ VARGUS on the distribution of tracts on sanitation, Dr. TOLOSA-LATOUR rose again to read a lengthy speech which he had had printed in French and in pamphlet form. He appropriately reminded the Congress that not only the medical press but the general press of France had been founded by a medical man—that was, by Théophraste Renaudot—who was a philanthropist, a doctor, a man of letters and a genial journalist, and whose statue ornamented one of the public squares of Paris. In Spain they could only show to the Congress the modest bust of a contemporaneous writer, Dr. Benavente, whose fine sense of irony and literary talents had endeared his memory to the Spanish people and had been transmitted to one of his sons. If the Spanish schools and the Spanish press did not display evidence of wealth they were not lacking in ardour and good intentions. But they had to borrow much from other nations and in their haste to translate good foreign works into Spanish they often committed regrettable errors. Then the speaker went on to describe how much better industrial property was protected than was literary property. In regard to the medical press they must not have, he argued, too many restrictions, for knowledge must spread. On the other hand, the journalist was ever seeking for a new idea, a new discovery, and to give it a body and a means of presentation. Journalists had thus often the opportunity of strengthening, improving, or rendering more comprehensible a new idea or discovery. Now, a chemist who made a new explosive became a millionaire, but a medical man who discovered a new microbe or how to perform a new and useful operation, or found a new remedy, received nothing for his reward unless he was able to give his discovery a commercial aspect and thus to obtain protection. At best he only received a very feeble reward and some belated honours. The man of science could only claim that his authorship of the discovery should be recognised; but however widely this discovery might be noticed in the press he received nothing for it. If Krupp made a large fortune why had not Pasteur been similarly fortunate? He then went on to urge that the pure scientific idea, apart from the manner in which it was clothed and described, should be recognised as a property by the International Association of the Medical Press. The man of science sowed and the journalist cultivated the soil and the two together created a value, a property, which they should strive to protect from the charlatan and the adventurer. It was the mission of the medical press to endeavour to secure for the author of the new idea or discovery full recognition and adequate reward.

Dr. BLONDEL, speaking next, said he was pleased to see these generous ideas coming to the front again. But who was the first inventor or who was first to conceive a new idea? The most recent inventions were modern adaptations of what was already partially and sometimes completely known. Then such recognitions of the supposed author of ideas would lead to terrible conflicts arising out of complex financial interests. They of the press, said Dr. Blondel, did their best to render justice to the authors of new and useful ideas and did not willingly misrepresent the facts. Sometimes they committed errors, but as a rule justice was generally done at least in the long run. The author of an idea might get protection if he formulated and published his idea. How was it possible to take into consideration that which had not been formulated?

Dr. FERNANDEZ agreed with Dr. Blondel; it was right in principle to protect the mere idea but it was not practical.

Dr. TOLOSA-LATOUR replied that he was aware of all these objections, but were they to leave the idea or discovery of the man of science at the mercy of the journalist? The man who wrote a summary of a lecture in which the new idea had been propounded acquired a copyright of this summary description but the inventor himself had nothing at all, neither copyright nor anything else. A man might make a drawing of the new idea, or if it was an instrument then the instrument maker might manufacture the instrument, the one sell his drawing, the other the instrument, and both received something, but the real author got nothing, neither payment nor protection.

Professor CORNIL said that he was pleased to have heard this discussion but he thought that the case was fairly met by Article 3 of the statutes as drawn up at Monaco, which stipulated that the real author should always be recognised. On the other hand, public lectures were public property, just as were the speeches delivered in Parliament. The professor, he maintained, had no right over his lectures; he could not reserve any portion of his lessons. That had been fully established by the French law courts. Public instruction should be given to all and belonged to all so that all might learn.

The Congress then adjourned for lunch, meeting again in the afternoon, when Dr. LARRA read a report on the Spanish medical press. It had been in existence some two centuries. There was a military medical paper published in Madrid in 1773.

Dr. BLONDEL followed on a professional point—namely, the publication in periodical papers of reports of the proceedings of learned societies. These societies themselves issued reports of their own proceedings but they appeared at greater length and at a later date, perhaps weeks or months afterwards. From one point of view this was an advantage, but the work was not so carefully done. On the other hand, the great teachers were also more careless than they used to be. They now contented themselves in going to some scientific meeting where they made a few extempore remarks, trusting to the medical press to preserve their teachings. Some very great men had never given anything else to the public. This was a degeneration, for it encouraged carelessness. Dr. Blondel thought it was a disadvantage to the press as well as to the publications of the learned societies. As a matter of news it was smart work to give quickly the gist of what had been said, but the more serious reviews that appeared once a quarter suffered. The great names that used to illuminate the pages of such publications did not appear so often and they no longer had so many careful studies from their pens. Some papers in France gave six or more columns to reports of meetings of the Academy of Medicine and many professors were now content to trust to shorthand writers and had ceased to write anything themselves.

Dr. POSNER thought the picture given was exaggerated. In Germany some papers were the organs of the great scientific societies and it was their business to give in full all that they could obtain. [illegible] The object was to give all new [illegible] It was the professors' and [illegible]ot write long and carefully-thought-out papers. In Germany the general complaint was that these papers were too long. A little clever, crisp summarising would be very welcome so long as due credit was given to the authorities quoted.

Dr. BLONDEL replied that reports now appeared in 24 hours instead of two months and these reports were often almost *verbatim*, so that they destroyed all hope of subsequent and more careful publication.

Professor CORNIL remarked that as opinions seemed to differ they must give liberty to each to do as he thought best.

Dr. VIDAL said that a sharp line of demarcation should be made between what was but the bulletin or circular of a society and what was a *bonâ-fide* journal.

Dr. AVILEZ remarked that a real transformation was taking place and Mr. ADOLPHE SMITH insisted that the business of the Congress was with medical journals and not with publications that consisted simply of the transactions or proceedings of some one society.

Dr. BLONDEL again spoke, remarking that in Belgium the medical press was in danger of extinction through the competition of bulletins issued by societies and sometimes distributed gratuitously. These publications commenced merely as records of the proceedings of the society by which they were published. Then it occurred to someone that it would be useful to have a few advertisements, and as advertisers preferred journals scissors and paste were employed, a few leaderettes were written, and the bulletin was transformed into what pretended to be a journal. These publications were pushing the legitimate journals out of the field, at least in Belgium. Now in France there was a medical friendly society, l'Association des Médecins de France, and it had about 8000 members. It used to publish a bulletin which contained balance-sheets, a record of the widows and orphans of medical men who had been helped through the agency of the association, &c. Now, and so as to recruit more members, this bulletin was being forwarded gratuitously to all the medical men of France; then, so that those practitioners who did not belong to the association might be tempted to read it and perhaps ultimately to join and further so that advertisers might likewise be tempted to advertise, this bulletin had been converted into something like a journal, for it now contained a few original articles. The speaker wanted to know if a bulletin was to be considered a journal.

Dr. VIDAL said that a bulletin was paid for by the society it represented, it had neither editor nor staff; what it published was signed by the secretary of the society it represented and for the society. Therefore it was not a journal and the secretary of the society was not a journalist.

Dr. PITALUNGA (Italy) said that the double character of medical man and journalist somewhat complicated matters, particularly as there were three different kinds of periodical publications to be considered. There was the doubtful bulletin, the organ of a society; then there were the archives or reviews, solemn and ponderous, and appearing perhaps only once in three months. The merit of such a publication depended entirely upon the master by whom it was controlled and who published only careful and elaborate studies. It was all a question of the responsibility of the master. For his sake, and his sake alone, were such publications bought, and they were useful, for sometimes the master brought out young men who otherwise would never get a hearing. Then there was the *bonâ-fide* journal. He thought that it was easy enough to distinguish between these three very different categories of publications.

At this stage the Congress adjourned for the day.

THE FOURTEENTH INTERNATIONAL CONGRESS OF MEDICINE, MADRID.

(FROM ONE OF OUR CORRESPONDENTS.)

EXCURSION TO THE SOUTH OF SPAIN.

MUCH has been written of the discomfort endured by some members of the Congress who have lately returned from Spain. In many cases the discomfort was born of an imperfect knowledge of Spanish combined with a laudable, if child-like, wish to manage for oneself and not to be helped. It is pleasant, therefore, to record the successful issue of the excursions to the south of Spain under the guidance of competent conductors who did not exceed the moderate cost at first agreed upon. There were several of these excursions so arranged in point of time that the "caravans," as such parties are called by the railway officials, worked independently of each other, visiting the same towns in succession. In every case the parties had to be small, for the hotel and railway facilities in Spain are not great. One through train runs in each direction daily and on three nights a week there is an express with sleeping-cars attached. The track is single and the halts are many and long. Early breakfast and *déjeuner* are taken *en route* at a wayside station with the guard, engine-driver, and fireman, whilst dinner is usually served in the hotel either before starting or on arrival at the destination. Through carriages are only to be obtained as a special favour, the number of places in each train is as fixed as it used to be in the diligences, trains cannot be multiplied to suit the traffic, nor is it usual to add a carriage when the train is full. It is necessary, therefore, to give ample notice when a caravan of even moderate size intends to travel Seats must be booked some days in advance and the heavy luggage may be required 12 hours before the train starts, a custom which affords ample opportunity for an unauthorised and furtive examination of the baggage in the early hours of the morning. Passengers are still penned up in stuffy waiting-rooms until the train starts and, more irritating than all, the booking office is closed with exemplary punctuality ten minutes before the advertised time of departure. There are, however, [illegible] the carriages are comfortable, [illegible] punctual, and as the [illegible] the country is seen at leisure.

A long night journey of 350 miles intervenes between Madrid and Seville, but the glories of the latter town amply repay the traveller for the discomfort of getting there. The magnificent Cathedral which overtops all the other buildings in the city, the Alcazar, or ancient royal palace, with its Moorish Hall of the Ambassadors and its lovely hanging gardens thronged with nightingales, the copy of Pontius Pilate's house, and the Torre del Oro where the gold of Mexico was stored on its arrival in Europe, make Seville the most interesting city in the south of Spain. The clean and narrow streets, the trim patios or forecourts of the houses, the shops open to the street as in a bazaar, and the dozens of barbers all plying their trade in full view of the passers-by were the first indications to the caravan that the customs of Paris and Madrid had been exchanged for an older and more picturesque civilisation. Three days were spent at Seville, one being a Sunday to give an opportunity of attending high mass celebrated most gorgeously and impressively in the Cathedral. Part of another day was devoted to visiting Italica which was founded by Scipio Africanus as a sanatorium for his veterans. A fine amphitheatre remains but there are not even ruins of the town where the emperors Trajan, Hadrian, and Theodosius first saw the light.

Three clear days did not exhaust the charms of Seville, for the whole time might well have been spent in the picture gallery amongst the Murillos which vie with, if they do not actually excel, the magnificent collection at Madrid. The fourth day was spent in traversing the 280 miles which separate Seville from Granada. The party was certainly routed and its individual members were nearly destroyed on their arrival by the touts of the different hotels in the town. But rooms had been secured in the Washington Irving Hotel within the grounds of the Alhambra and after a very late dinner most of the caravan went to bed, preferring to imagine rather than to see the beauties of the ancient Moorish palace as revealed by the light of a full moon. The next day was devoted to an exploration of the Alhambra, but it was not seen to the best advantage, for the weather was cold and dull, whilst the beggars were noisy and importunate. The beautiful gardens of the Generalife were visited and as a point of honour a drive was taken through the gipsies' quarter. The visit was not made without some trepidation on the part of the ladies, for one party had an escort of soldiers and another had ominous tidings of the newly committed murder and robbery of a Spanish gentleman who had been quietly returning home on the previous evening. The gipsies appeared, however, as picturesque villains dwelling in caves much after the fashion of our ancestors, but with greater conveniences, prolific in children much given to halfpence and posture dances.

The caravan proceeded from Granada to Cordova, a distance of 140 miles, at the leisurely rate of ten miles an hour, a speed which gave ample time to survey the beauty of the Sierra Nevada, the constant covering of snow of which must be so grateful a sight to the inhabitants of the hot and wide plain beneath. The mosque at Cordova surpassed even the extravagant expectations which had been formed about it, so that the sightseer was prepared to condone vandalism which had built a great Christian church in its very midst, for the very size of the church revealed the immensity of the mosque within which it was hidden. The mosquitoes here became troublesome and there were few who did not welcome the time when they climbed into their sleeping-berths at Cordova to awaken in the plains of La Mancha whilst passing windmills any of which might have been successors to those tilted at by Don Quixote. The morning café was enlivened by the report that as the train had been overcrowded on the previous evening the night had been spent in depositing 30 or 40 would-be passengers at different wayside stations to reach their destinations as best they could and to learn the lesson that seats in a first-class train on a Spanish railway must be booked beforehand. The return journey from Madrid was as straightforward as the outward journey had been, for the Sud Express has admirable accommodation both for sleeping and refreshment. The caravan reduced itself to constituent units at Biarritz.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

An Eye Infirmary for Bangalore.—The Indian Medical Services.—The Increasing Plague Epidemic throughout India.—Accidents in the Streets of Indian Cities.—The Practice of Sati in India.

AN eye infirmary, estimated to cost Rs. 150,000, will shortly be built by the Mysore Durbar in connexion with the Victoria Jubilee Hospital erected during the late regency on the *glacis* of the Bangalore fort.

The proposal to form one body out of the various subordinate medical services in India by combining them into a single corps under the title of the Indian Army Medical Corps has been finally negatived.

The following figures are interesting as showing how the plague epidemic has spread in India during recent years. There were in 1897 56,000 recorded deaths; in 1900, 93,000; in 1901, 274,000; and in 1902, 577,000. During the first three months of the present year the mortality was 334,000, that in March last being no less than 136,000. The reduction in the plague mortality throughout India reported for the week ending April 11th has not been maintained. Once again a marked rise to 32,159 has occurred which is more than accounted for by the Punjab alone, where the plague mortality is now greater than in all the rest of the country put together, having gone up from 13,225 to 18,488. This is the history of last year repeating itself. There was an increase of about 1000 deaths in the United Provinces, bringing the total there to 4382. The counterbalancing decreases occurred in the Bombay presidency and in Bengal. In the United Provinces 12 cities are now suffering, including Allahabad, Agra, Benares, Cawnpore, Lucknow, Meerut, and Bareilly. The disease is now raging very fiercely in Karachi, but there are better returns from Bombay city and from Calcutta. The severe and continued prevalence of plague in Bombay city has led to the enlargement of the Marathu Plague Hospital. Five new wards have just been opened. They have been presented by some of the leading inhabitants and are constructed of red brick with Mangalore tiles and neat paving. They will prove a great improvement on some of the existing sheds. This hospital in Bombay has always been popular, the reasons given being that it is cheerful in appearance, is centrally situated, and is of sanitary construction; that there is an option given to all patients of native or European treatment; and that there is great freedom of access for the relatives.

The frequent accidents in the streets of the two cities of Calcutta and Bombay have drawn attention to the imperfect means in both cities for the conveyance to hospital of injured or sick persons. There are very few ambulances in Bombay and still fewer in Calcutta and the delay which occurs when there is an accident is a matter of public comment in both cities. Some attempt is about to be made in Calcutta to remedy this grievance, but unless the police are made responsible for the removal to hospital of these cases the provision of ambulances will not be of much avail. At present in both cities the want of the necessary organisation and material is a disgrace.

Although Sati or the burning of the widow on the funeral pyre of her husband was prohibited by the Government many years ago the practice is occasionally kept up in out-of-the-way places and in secrecy. This shows that the custom still lingers and the manner in which it is referred to by the native press also shows the underlying sympathy with this horrible form of cruelty. Although burning is now rare, the suicide of widows in other ways has to a certain extent taken its place, and every widow who kills herself on the death of her husband is styled a heroine. There is a widely-rooted idea that the wife should not outlive her husband and it is probable that if British rule were removed the old practice would be revived. The ideas are said to be founded on religious sanction, but the putting to death of innocent young lives ought not to be tolerated. If Hindu society cannot purify itself from such barbarous customs it will never gain the respect of educated and right-thinking persons, and if the encouraged practice (and it is apparently encouraged very strongly) continues the Government of India may be called upon to interfere.

April 30th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Manchester Coronership.

EVER since the death of Mr. Smelt, the late Manchester city coroner, there has been a good deal of interest shown as to the appointment of a successor. Some weeks ago the town hall committee of the county council, to which the preliminary task of making a selection to be afterwards submitted to the council was committed, reduced a list of 26 applications to six and then recommended a member of the medical profession for the office. There was no question as to his fitness, although he had had no previous experience of the work, but unfortunately he was at the time of his application as a candidate a member of the council and a member of the committee by which he was recommended for the coronership, although he afterwards resigned his membership of the council. At the subsequent meeting of the council the recommendation of the town-hall committee was set aside, as his appointment would have been on the extreme verge of legality if not absolutely illegal, and the matter was referred to a new committee specially chosen. This committee on May 8th selected six names from the original 26, setting aside the gentleman recommended by the town-hall committee and also another who is one of the legal staff in the town-hall, and substituting the names of two others of the candidates. After seeing each of the six, votes were taken and after the preliminary rounds there were 11 votes for Mr. Gibson and eight for Dr. Sellers and then the committee voted unanimously for Mr. Gibson who was chosen for the approval of the city council. Though it is not absolutely certain that the choice of the committee will be approved at the council meeting to be held to-morrow it is almost certain, for this time there is no illegality to bar the way, and Mr. Gibson comes with good credentials. He was educated at Trinity College, Cambridge; is B.A. and LL.B. with honours in the Law Tripos in 1883. He was called to the bar and practised at the bar of the Northern Circuit in Liverpool. In 1898 he began to study medicine at University College, Liverpool, and has passed all the examinations for the M.B. and Ch.B. except the last part of the final, for which he is not entitled to enter until July. He has been deputy coroner for Liverpool since 1892 and has conducted over 3000 inquests. "He stroked his college boat at Cambridge and he devotes holidays to mountain climbing." As there is only one coroner for Manchester it was certain that 25 out of the 26 candidates, many of whom were notably well qualified, would be disappointed, and one can only express sympathy with the unsuccessful.

A New Hospital for Skin Diseases.

The Manchester and Salford Hospital for Diseases of the Skin, established in 1884, has outgrown the accommodation to be found at the modest building in Quay-street and a new hospital is to be provided. It will have a frontage to Quay-street and Byrom-street, and will accommodate 28 in-patients and a large number of patients for "light treatment." The out-patients' waiting-hall on the ground floor is planned for 200 patients and suitable consulting rooms are connected with it. The appliances for "light treatment" will be used on the first floor and the in-patients will be on the second floor where three pavilion wards are grouped in separate wings. The cost of the buildings is estimated at about £14,000.

John Dalton.

To-day and to-morrow the Manchester Literary and Philosophical Society celebrates the centenary of the announcement of the atomic theory by John Dalton, the most distinguished of its presidents. This afternoon Professor F. W. Clarke of Washington, U.S.A., will deliver the Wilde lecture on the atomic theory at the society's house in George-street. This will be followed by a dinner in the evening, quite in harmony with Dalton's views. For we are told that in his simple and regular life his "only diversion from chemical experiment was the game of bowls, which he played with infinite zest on the green of the Dog and Partridge near Stretford, every Thursday afternoon." After undergoing this exertion "he would go home to consume the food needed to supply the metabolism of the body and to sleep in order to obtain further nerve power for the next day's brain work." In this case the next day's work will be a degree ceremony of the Victoria University in the Owens College, when Earl Spencer will confer the honorary degree of D Sc. on Professor Clarke and on Professor I. H. Van't Hoff of Berlin. This is not the place to give even a slight sketch of the career of the Quaker philosopher, but the story of his one love affair—which came to nothing, for he never married—is so quaint as perhaps to excuse its appearance here. He became attached to a lady who was accounted the "handsomest woman in Manchester." But as he wrote to his brother he felt himself secure against mere beauty, but "she began to descant upon the excellence of an exact acquaintance with English grammar and the art of letter-writing; to compare the merits of Johnson's and Sheridan's dictionaries; to converse upon the use of dephlogisticated marine acid in bleaching; upon the effects of opium on the animal system, &c., &c. I was no longer able to hold out but surrendered at discretion" He died in July, 1844. His remains were placed in the old Town Hall and it is said that 40,000 persons went to pay their last tribute of respect "to the Quaker chemist who had made Manchester famous throughout the whole learned world."

Manchester Infirmary Site.

The petition of the Manchester corporation for the insertion in the Bill now before Parliament of an additional provision relating to its acquisition of the site of the Royal Infirmary was yesterday before the examiner of standing order proofs. *In point of time* as to the publication of notices this provision of the Bill had not, of course, complied with standing orders and the examiner will so report to the committee which will be asked to dispense with these formalities and will, no doubt, accede to the petition.

New Hospital for Mid-Cheshire.

On May 8th Mr. J. Cawley, architect, was appointed to carry out the erection of the joint hospital. It is to have 34 beds, and the cost, exclusive of site and furnishing, should not exceed £8500 or £250 per bed.

Small-pox Costs.

The anti-vaccinationists will, no doubt, be delighted to see that the estimates for vaccination fees and expenses for the half year, for the four unions of Manchester, Salford, Chorlton, and Prestwich, *owing to the persistent lingering of* small-pox, amount to £5800.

May 19th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Workhouse Nursing.

THE recently issued report of the Local [illegible] Board departmental committee which was appo[illegible] quire into the nursing of the sick poor in workhouses was under discussion at Malvern on May 12th at the annual conference of Poor-law guardians from the West Midland district. Dr. Arthur H. Downes, one of the Poor-law inspectors of the Local Government Board, at the outset pointed out with satisfaction that within the past seven years there had been an increase of 52 per cent. in the number of paid officers engaged in nursing the sick in England and Wales, an evident *proof of the efforts of guardians to provide* paid and re*sponsible nurses in the place of unpaid and irresponsible* inmates. The increase had been more especially noticeable in the country workhouses. Dr. Downes then dealt with the difficulties attending not only the procuring of nurses but also in retaining their services. He urged boards of guardians to provide comfortable quarters, varied food, sufficient recreation, and not to overwork *their nurses. He also advocated the establishment of* training schools for nurses and emphasised the importance and *necessity in the interests of economy of having a* whole-time medical officer in all large workhouses. The departmental committee, he said, considered that in workhouses where the average daily number of sick was below 100 the matron, if properly trained and with suitable assistance, might act as superintendent nurse. The experience of the *Atcham union in Shropshire* and *of the Stoke-on-Trent union* with regard to the adoption of the recommendations of the departmental committee differed in a remarkable degree. The chairman of the Atcham board of guardians said that within the past few months seven superintendent nurses had come and gone at the Atcham workhouse and the board had found the greatest difficulty in obtaining nurses. The clerk to the Stoke-on-Trent union, which is one of the largest in *the country, related, on the other hand, an entirely different* experience and he thought that the fact of there being a nurses' home at Stoke-on-Trent was one reason why nurses stayed with them a considerable time and why they had no difficulty in obtaining a supply of nurses. Miss Gibson of the Birmingham Infirmary considered that it was quite impossible to train a nurse properly in an institution with only 60 or 100 patients. She was of opinion that no nurse should be appointed to a workhouse who had not been at least one year in a training school.

Imprisonment under the Infectious Disease (Notification) Acts.

A medical man lately practising in the Rhymney valley has suffered imprisonment for failing to comply with the requirements of the Infectious Disease (Notification) Acts. For neglecting to notify a case of infectious disease to the medical officer of health the gentleman in question was called upon to appear before the magistrates and in spite of his protestations that he had acted quite inadvertently and, indeed, that he had actually written out the certificate but had forgotten to post it, a fine was inflicted with the alternative *of a month's imprisonment.* As he declined to pay the fine he was taken to Cardiff gaol on May 9th but was released three days later after his friends had paid it.

Cardiff Grouped Poor-law Homes.

The Poor-law guardians of Glamorganshire have long recognised the desirability of taking the children under their care away from the workhouses. At Pontypridd, Bridgend, Neath, and Swansea grouped homes have been in use for several years and on May 13th the Cardiff board formally opened similar homes at Ely, an outlying district of the town. The Ely houses include two semi-detached and two detached cottages, each with accommodation for 12 children, and there is one larger house with room for 24 children. There is thus provision altogether for 72 children. In addition to these buildings there are a house for the superintendent, a store house, a small hospital, and suitable playgrounds. The cost of the scheme is about £8000 There are also in the Cardiff union 234 children living in 24 scattered homes. So long ago as 1863 the Cardiff workhouse children were housed in separate school buildings at Ely and these will now be used as an auxiliary workhouse.

Rural Water-supplies.

Rural district councils as a rule place a very broad interpretation upon the provisions of section 6 of the Public Health (Water) Act, 1878, which prohibits the occupation of [illegible] within a reasonable dis- [illegible] *wholesome water. It* [illegible] when the members of [illegible] effect to this section they are not supported by the local bench of magistrates.

The St. Mellons (Mon.) rural district council recently refused a certificate of occupation for a newly erected house within its district on the ground apparently that although there was a well on the premises the medical officer of health (Mr. W. E. James) reported that the water could become polluted by surface drainage and the supply was not a proper one. The owner of the house thereupon appealed to the justices who decided that the house might be occupied.

Typhus Fever and Small-pox at Cardiff.

Until the past few weeks typhus fever had been absent from Cardiff for many years. During the second week of April a case was reported in the town, and three weeks later it was found that four more persons were suffering from the disease. The outbreak has been traced to a man who came from Liverpool where 120 cases have occurred during the present year. At the beginning of May there was a recrudescence of the epidemic of small-pox in Cardiff which has been attributed to a barber who had been carrying on his business for nearly a fortnight while suffering from a mild attack of the disease. Altogether ten persons were infected from this source.

An Honorary Degree for Lord Lister.

At the congregation of the University of Wales which will be held at Cardiff in November next Lord Lister and Lord Kelvin will have conferred upon them the honorary degrees of doctor in science. The resolution relating to Lord Lister was unanimously passed at the annual extra collegiate meeting held on May 14th at Llandrindod and referred to his "long-continued scientific research which, by establishing a system of antisepsis, has revolutionised the practice of surgery throughout the world."

Notification of Measles.

At the meeting of the Midsomer Norton (Somerset) urban district council held on May 11th it was decided to include measles under the diseases which are notifiable under the Act of 1889 for the ensuing five years. A letter was read from the Local Government Board stating that the Board had the subject of the notification of measles generally under consideration and that the advantages from the addition of measles to the list of notifiable diseases were largely dependent on the notification, together with the attendant measures of prevention, being maintained for a reasonable number of years.

Vaccination Grant.

Mr. J. Dibble Staple, the public vaccinator for the Ashley district of the Bristol union, has been awarded the grant for successful vaccination by the Local Government Board for the third consecutive time.

May 19th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Visit of the King and the Queen to Glasgow.

GLASGOW on May 14th was happy in being honoured by a visit from the King and the Queen and the city, in spite of the unpropitious weather, showed itself to as great advantage as possible. Dense crowds thronged the entire length of the route which their Majesties took through the city and at every point they were received with the greatest enthusiasm and loyalty. The arrangements were perfect and the whole proceedings passed off without any serious accident to mar the success of the visit. The King on this occasion was pleased to lay the memorial stone of the new technical college in George-street. This ceremony took place before a large and representative gathering of the citizens, there being invitations issued to over 2500 guests. Glasgow has always been acknowledged as the commercial capital of Scotland and it is a matter of extreme satisfaction to the whole community that the Royal visit has been associated with an event so auspicious and one which must prove of good augury for the future of technical education in general and of this school in particular. Their Majesties during their progress through the city visited the new art galleries where the scene, in spite of the unfavourable weather, was very brilliant. They visited also the University, the foundation-stone of which was laid by themselves (as Prince and Princess of Wales) 35 years ago. Lord Balfour of Burleigh, the Secretary for Scotland, in the presence of a large gathering in front of the University, introduced Principal Story who, on behalf of the University authorities, briefly thanked their Majesties for honouring the University with a visit and presented an address. The King, in replying, recalled with satisfaction his own share in laying the foundation-stone of the noble building and recognised it as a true symbol of the greatness of the University which had adapted itself to the commercial expansion of the city. In concluding he expressed the earnest desire that this university and other universities as schools of higher learning might grow and prosper and so advance the material prosperity of his people.

Small-pox in Scotland.

On May 18th the Local Government Board of Scotland intimated that during the period from May 1st to 15th inclusive five cases of small-pox had been notified to it from the burgh of Dundee and one from the burgh of Glasgow.

May 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Medical Association.

A MEETING of medical men, chiefly belonging to the Poor-law medical service of Belfast and surrounding districts, was held in the Medical Institute, Belfast, on May 6th, to consider the advisability of forming a Belfast and District Branch of the Irish Medical Association. There was a large attendance and on the motion of Dr. A. Mussen, J.P. (Glenavy, co. Antrim), seconded by Dr. D. P. Gaussen (Dunmurry), Professor J. W. Byers was called to the chair. Dr. A. Gardner Robb (honorary secretary *pro tem.*) having read several letters of apology from medical men unable to be present, Professor Byers, after thanking those present for asking him to preside, said that it was of the utmost importance that the grievances under which the Irish Poor-law medical officers laboured should be made public in order that they might be redressed. He said that these grievances were, in the main, inadequate remuneration, no fixed holidays, and no superannuation. So long as these grievances remained such a state of affairs was bad for the medical men concerned, degrading to the Poor-law medical service in Ireland, and injurious to the best interests of the country. An underpaid and overworked service would in the end be avoided by young men of ambition and ability starting life. He believed these grievances could be got rid of in two ways: (1) by the policy at present advised by the Irish Medical Association of the members of the medical profession combining and refusing to offer themselves as candidates for any vacancies that may arise until the authorities in the interests alike of the people as well as of the profession decided to improve the conditions of the service; and (2) by the help of the profession outside the Poor-law medical service. It was the bounden duty of every member of the profession to try to remove the grievances that pressed hard on any member of it and above all to bring contentment and happiness to all those who practised it. Speaking as one outside the Poor-law medical service he could promise that every help would be given to the dispensary medical officers of Ireland by all branches of the medical profession until their grievances were redressed. It was then decided to form a Belfast and District Branch of the Irish Medical Association and the following office-bearers were appointed:—President: Professor Byers. Vice-President: Dr. S. B. Coates. Secretary and treasurer: Dr. Robb. Members of Council: Dr. W. R. Davison (Ballymena), Dr. J. St.C. Boyd (Belfast), Dr. Mussen, Dr. J. M. Killen (Larne), Dr. Gaussen, Dr. J. J. Adams, J P. (Ashville), Mr. J. D. Osborne (Belfast), Dr. J. McLiesh (Belfast), Mr. H. C. Manley (Whitehouse), and Dr. R. J. Munn (Belfast). The president, vice-president, and secretary, with Dr. Adams, Dr. Gaussen, Dr. Davison, and Mr. R. Currie were appointed delegates from the branch to the annual meeting of the association to be held in Enniskillen in June. The next meeting of the branch is to be held on June 30th.

Dispensary Contest in the Ardee Union.

For several months the position of dispensary officer to the Drumconrath district of the Ardee Union, co. Louth, has been vacant. The original salary was £120 per annum, with £30 as medical officer of health. In October, *1902*, the guardians advertised the position at the old salary but there were no applicants. They refused to revise the salary and postponed making any appointment for several months They advertised again at the old salary and on May 5th there were two applicants—one from Lucan and Mr W H Crean, medical officer at the Ringville Dispensary, Dungarvan, co Waterford, who was elected Had the salary been raised to £200, the minimum suggested by the Irish Medical Association, two local men would have applied, but they loyally adhered to the resolution of the local branch of the association and did not apply for the position Although this appointment may in one sense be regarded as a victory over the Irish Medical Association it is satisfactory to find that 10 of the guardians voted for making no appointment, while those who elected Mr Crean numbered 16

Royal Victoria Hospital Belfast

At a largely attended meeting of the board of management and life governors of the Royal Victoria Hospital, Belfast, held on May 6th Dr J S Morrow was appointed assistant physician, Mr J A. Craig assistant ophthalmologist, and Mr R J Johnston assistant physician for diseases of women Dr S Blakely was appointed house surgeon

The Sanitary Condition of Newry

Dr C J Clibborn (Local Government Board medical inspector) has reported to the Newry urban council that the sewerage of the Armagh side of the town of Newry is very defective If the sewerage of the town were improved, the removal of refuse through dwelling houses stopped, and a better class of privies built Dr Clibborn thought that the number of cases of infectious diseases would be lessened He also recommended an ambulance for the conveyance of patients with infectious disease

Pulmonary Tuberculosis in the Belfast Workhouse

A deputation from the Belfast board of guardians met the members of the public health committee on May 7th to discuss the steps to be taken to deal with the large number of consumptives in the Belfast union workhouse, when it was decided to appoint a committee of both boards to go fully into the question

The Poor law Guardians in Ireland and the Medical Profession

The constant friction between the medical profession and the Poor law guardians in Ireland continues Here are the latest examples As appears in THE LANCET of May 9th, p 1340, a meeting was held in the Medical Institute Belfast, on April 30th to form a North Down Branch of the Irish Medical Association at which Dr F P MacLaughlin and Mr J W Olpherts were present The attention of the Downpatrick guardians having been called to this circumstance the clerk was directed to write to ask these gentlemen for an explanation why they left their districts without having first notified the board of guardians or the relieving officer Mr Olpherts replied that during his few hours' absence on April 30th he left the district in charge of a thoroughly competent medical man and by arrangement, as to why he left his district it was, he wrote, to attend a meeting in Belfast to form a branch of the Irish Medical Association and to defend professional interests In the other case Dr E C Thompson M P, complains in a letter to the Omagh board of guardians that at its last meeting it perpetrated on him a most unmerited insult and one which he bitterly resents It appears that Dr Hans B Fleming, who had been ill four days before the meeting of the board owing to an unfortunate accident, nominated Dr Thompson as his substitute at the workhouse (a position he had on many previous occasions taken for him) and without a word of explanation the guardians dispensed [illegible] medical man in his place [illegible] he had acted on many other [illegible] out fee, yet upon the first oc [illegible] the guardians might have been called on to pay for a substitute for Dr Fleming they turned [illegible] appointed another medical man [illegible] this action on the part of the [illegible] ignorance and inexperience' in dealing with such matters and he demands a cheque for £12 12s for his four days' attendance at the workhouse, which the board says it could not entertain the idea of paying It is to be hoped that Dr Thompson will press his claim

Tuberculosis in Ireland

The committee of the Dublin branch of the National Association for the Prevention of Tuberculosis has recently issued a little book entitled "Consumption and its Prevention" in which the fact is emphasised that while consumption is decreasing in England, Scotland, and Wales there is still a steady increase in Ireland It appears that between the ages of 24 and 35 years almost one half the deaths are due to consumption which caused an eighth of the entire death rate of the country The authorities of the National Education Office have undertaken to circulate this pamphlet amongst the managers of schools under the board and between 10 000 and 15 000 copies will soon in that way be distributed over Ireland

Alcoholic Cirrhosis and Crypto tuberculosis

AT the meeting of the Hospitals Medical Society held on May 1st M André Jousset gave the result of some experiments which he had made with a view of elucidating the rôle played by Koch's bacillus in the production of hypertrophic alcoholic cirrhosis He had found that the ascitic fluid which accompanies this kind of cirrhosis very frequently contains bacilli, while the same thing apparently exists with regard to the spleen In two cases inoculation with hepatic parenchyma after the blood vessels of the glands had been washed out had caused a guinea pig into which it was injected to became tuberculous and the same thing happened in [illegible] injection of spleen pulp M [illegible] on the importance of these [illegible] explained in some degree the nature of numerous obscure febrile attacks and also showed that these bacillæmias were curable at least for a time M Mosny said that, he did not think that the simple presence of Koch's bacillus in the effusions was enough to enable the observer to say that the disease was really tuberculous For instance, there were very many cases where some disease, such as acute pneumonia or hepatic cirrhosis lighted up a tuberculosis which had hitherto been only smouldering In these sort of cases there was a secondary tuberculisation of a diseased condition which was originally of a totally different nature M Bezançon agreed with M Mosny and referred to cases of cancer, of secondary tuberculosis and of leukæmia complicated with other kinds of infections He further remarked that it was known to be difficult to differentiate Koch's bacillus from acid resisting bacilli M Chauffard asked whether these acid resisting bacilli could not closely resemble tuberculous bacilli found in the sputum The question, he thought, was very important

Physiological and Therapeutical Action of Cecropia

At the meeting of the Biological Society held on May 2nd Mr Gilbert and Mr Carnot described the investigations which they had made with regard to the physiological and therapeutical properties of a foreign plant called cecropia The alcoholic extract which they employed was of comparatively low toxicity and could be used in large doses without the production of untoward symptoms Cecropia, like digitalis, seems to be cumulative in its action a property which explains the persistence of its effects for a period of several days It acts on the heart principally by increasing the energy of contraction of the cardiac muscle As shown on sphygmo-manometric tracings, the amplitude of the pulsations is doubled, tripled, or even increased to a greater degree and this effect persists for a somewhat long time, when poisonous doses are given the pulse becomes slow and its tension is reduced Cecropia acts on the kidneys as a diuretic and may increase the flow of urine to three or four times the normal amount. In their clinical trials of cecr [illegible] alcoholic extract to [illegible] having extreme weal [illegible] 30 drops every 24 hours continued for four or five days. On and after the third day there was copious diuresis A patient who had been passing only 500 cubic centimetres (17½ fluid ounces) of urine daily and had taken cecropia for five days passed 700 cubic centimetres on the second day, 2500 on the third, 3100 on the fourth, 2800 on the sixth and 2500 on the seventh The patient's general condition improved at the same time, his dyspnœa was less urgent, and his pulse, which at first could not be counted, became slower and regular This very remarkable effect was obtained almost invariably and was comparable to that of digitalis. Cecropia is, however, much less poisonous than digitalis.

Obituary.

Dr. Dreyfus-Brisac, physician to the Hôpital Beaujon, whose death is announced, was born in Strasbourg in 1849 and in 1869 was "externe" at hospitals in that city. He served as a volunteer in the Franco-German war in 1870 and after the annexation of Alsace-Lorraine to Germany he removed to Paris where he took his medical degree in 1878 and became hospital physician in 1880. He took a great interest in questions relating to poor relief and was a member of the conseil supérieur of the Assistance Publique. He was created Chevalier of the Legion of Honour in 1893.

(FROM OUR OWN CORRESPONDENT.)

Nerve-grafting.

Professor Körte and Professor Bernhardt have recently published in the *Deutsche Medicinische Wochenschrift* a case in which a divided facial nerve was successfully dealt with by grafting it on to the hypoglossal nerve. The patient was a woman, 38 years of age, suffering from inflammation of the left middle ear, which she said had come on after "influenza." Paracentesis of the tympanum had been performed without success and the suppuration and fever continued so that the radical mastoid operation became necessary. In the course of the operation it was found that the anterior wall of the lateral sinus was covered with granulations and that there was pus between the sinus and the bone. In the removal of the diseased bone the sinus was fully exposed to view as far as the jugular foramen and the base of the petrous bone was removed nearly to the carotid canal. The facial nerve was cut through close to the stylo-mastoid foramen and the posterior wall of the cartilaginous portion of the meatus was divided. The large cavity thereby produced was then washed out and drained with strips of iodoform gauze. The peripheral extremity of the facial nerve was now exposed as far as the parotid gland, after which, by means of a curved incision, the hypoglossal nerve was brought into view where the digastric muscle goes across and was traced upwards towards the base of the skull. The peripheral extremity of the facial nerve was then attached laterally to the trunk of the hypoglossal nerve with two fine catgut threads. The wound in the neck was sutured and primary union followed. After the operation there were complete paresis of the left facial nerve and partial paralysis of the left hypoglossal nerve; the tongue when protruded showed a slight deviation to the left and there was also some difficulty in swallowing. The operation was performed by Professor Körte on Dec. 20th, 1901, and on Feb. 3rd, 1902, Professor Bernhardt found that the left facial nerve remained completely paralysed, that with the induced electric current there was no reaction in the area supplied by the left facial and hypoglossal nerves, but that with the battery current there was a retarded "closing contraction." There were, in fact, the typical reactions of degeneration. The deviation of the tongue towards the left and the atrophy of its left side were still obvious. Electricity (constant current) was then applied daily but without apparent result until June 18th, when Professor Bernhardt for the first time observed traces of return of movement in the muscles of the left corner of the mouth. In the beginning of December the reaction of degeneration had disappeared but the reaction to both the battery current and the induced current was only slight. When the patient tried to move her tongue the facial muscles participated in the movement of the tongue and *vice versâ*. There still remained some paresis of the facial muscles on the left side, but voluntary movement of the left corner of the mouth and of the tongue was possible. The case showed that the power of coördinate movement might be restored after nerve-grafting. Similar results have already been obtained by Manasse and by Dr. Robert Kennedy of Glasgow,[1] both of whom united the facial nerve and the spinal accessory. It is of physiological interest to observe that in the above cases the hypoglossal centre or the spinal accessory centre became competent to supply the innervation of the facial muscles which had previously been supplied by a quite different centre.

Sanitation in Health Resorts.

The Prussian Minister of Public Instruction in his capacity of chief of the Government medical department has issued regulations relative to the sanitary arrangements of health resorts and spas. Every health resort in which, or in the vicinity of which, there is no hospital must provide accommodation for the temporary isolation of persons suffering from infectious diseases and must also provide a place suitable for the reception of the bodies of patients who may die. Apparatus for disinfection is kept in the more important health resorts but will now have to be provided by the smaller ones as well. For the latter disinfection by means of formalin is recommended on account of the necessary apparatus being moderate in price and easy to manage. The work of disinfection must be done by a public official and in places where such an appointment has not yet been made the Minister recommends that a suitable person should receive instruction in the duties free of charge in the hygienic institution under the control of a university or a province. In health resorts disinfection must be carried out not only in the cases in which the law already requires it—as, for instance, in scarlet fever, diphtheria, small-pox, and enteric fever—but also in pulmonary tuberculosis. Spittoons are to be provided in public places and buildings and notices are to be displayed requesting persons to refrain from spitting on the floor. Arrangements are also to be made for rendering first aid in accidents; moreover at seaside resorts the necessary requisites for the resuscitation of cases of apparent drowning are to be provided.

May 18th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Plague.

THE bubonic plague seems to be dying out in all the States. A case occurred at Geraldton, West Australia, on board a steamer from Singapore and was diagnosed as fever. On arrival at Fremantle the case was pronounced to be one of plague and the vessel was quarantined. No other case has occurred. Rats examined at Brisbane have been found to be infected with plague. Rigid precautions are still taken by the health authorities in all the States to prevent the introduction of the disease and to insure cleanliness and destruction of rats.

Typhoid Fever.

Typhoid fever has been prevalent in some parts of New South Wales, especially Coonamble and Balmain. 135 patients in the Coonamble Hospital are affected with typhoid fever. At Balmain it was proposed that the aldermen themselves should make a house-to-house inspection as the sanitary inspectors were too busy.

Lunacy Administration in Victoria.

In reply to questions in the Legislative Assembly of Victoria the Chief Secretary recently stated that the Victorian asylums had fewer medical officers than the New York State asylums, but the position of many of the American officers was very junior and they were paid low rates of salary. The English asylums had about the same proportion of medical staff as Victoria, but in the former place the medical superintendents were paid very much more than in the latter. A slightly larger number of attendants was allowed in America than in Victoria and the question of providing an adequate staff for the asylums was now under the notice of the Public Service Commissioner. The training of the attendants was in the hands of the medical staff and there was a probationary service of 12 months, during any portion of which time inefficient employés might be removed. As there were very few applicants for the position of junior medical officer it would appear that the medical staff was underpaid or that some other drawback existed, as the juniors actually got more pay than in England or America. Mechanical restraint of patients had in the past been much resorted to, but for the past three years special attention had been given to its reduction. Arrangements had been made for trained female nurses in the male hospitals, but at present the male hospitals at Kew and Yarra

---

[1] Proceedings of the Royal Society of London, 1900; Philosophical Transactions, 1901; see also THE LANCET, Feb. 17th, 1900, p. 449.

Bend were in charge of men who were there for some years and who were specially appointed as being suitable. Subsequently a deputation from the Medical Society of Victoria waited on the Chief Secretary and urged the necessity for immediate and extensive reform in the treatment of the insane in Victoria. The president, Mr. R. Hamilton Russell, stated that the Medical Society of Victoria regarded it as established that the present asylums in Victoria were lamentably behind the times in many fundamental respects, that there was pressing need for the better treatment of early and doubtful cases of insanity, and that there was an urgent necessity for suitable provision for insane patients whose relatives were able to contribute at higher rates of maintenance as distinct from the large number who by reason of their poverty were legitimate objects of State charity. There was also serious overcrowding, the ill-effects of which were aggravated by structural unfitness and insanitation. The staff, both medical and general, was inadequate and was subject to no proper mode of selection, training, and promotion. This defect was further aggravated by the fact that promotion in all classes went by the rigid rule of seniority, irrespectively of efficiency, and that officials once installed were practically irremoveable. The society believed that the present regrettable condition of affairs would continue so long as responsibility was divided, as it was at present, between inspector, Under Secretary, Chief Secretary, and Public Service Commissioner. The remedy was to place the entire control of all asylums in the hands of a lunacy board of three which should comprise the inspector and the Master in Lunacy, with a third member. For the better treatment of early and doubtful cases of insanity the establishment of a receiving house was essential. It was also considered that there was urgent need for enabling patients who were in a position to pay higher rates of maintenance to be treated in institutions other than those devoted to the cure of the legitimate objects of State charity. Until the Government saw its way to establish an institution for this purpose the society suggested the legalisation of properly licensed private institutions. Professor H. B. Allen said that of every 1000 [illegible] were relieved from their [illegible] 420 were curable, but [illegible] onditions obtaining in Victorian asylums were not conducive to cure. In reply the Chief Secretary said he did not think that trained attendants were necessary or that those in the Victorian asylums were incompetent. He approved of the establishment of a receiving house and a sum of money had been voted by Parliament for the purpose and a site had been selected at the Royal Park. He also thought that power should be given to the Government to license asylums under private supervision.

Proposed Hospitals for Consumption.

Last year the Government of New South Wales proposed to establish a hospital for consumption at Khuring-gai Chase, near Hornsby. The residents strenuously objected and the proposal was dropped. It has been recently revived and the residents have held an indignation meeting and arranged for a monster deputation to the Premier objecting to the proposal to establish a hospital to accommodate 300 incurable cases of consumption on a site of only 50 acres, close to a large population, while other and better sites were available.—Alderman Dr. W. Camac Wilkinson at a recent meeting of the Sydney city council secured the reference to the proper officers of the council of the question of the power of the council to expend money for the prevention of the spread of consumption, and on the cost of a site and of the erection of a dispensary for the treatment of consumptive cases. His suggestion was for the establishment by the council of such an institution in the city. Such an establishment would, he contended, be the first link in a chain, as it would lead to voluntary notification, which would be followed by instruction to the sufferers and their friends and in turn by inspection and disinfection of premises.

Medical Women and Hospital Appointments.

A deputation from the Progressive Women's Association recently waited on the President of the Board of Health of New South Wales to request that medical women should be appointed in all public institutions. The President replied that he had appointed a medical woman at the Coast hospital, the only institution over which he had control.

Preservatives in Food.

The duty of regulating the use of preservatives in food is laid upon the Board of Health by the Public Health Act of New South Wales and the question has been under consideration for some time. Regulations have now been published dealing with the matter. The substances which are regarded as preservatives are formic aldehyde, boric acid, hydrofluoric acid, sulphurous acid, benzoic acid, and salicylic acid. This list will be added to from time to time. Four of these substances which may be used are given and the proportions in excess of which they may not be used are fixed. The proportion is per pint of liquid or per pound of solid food and the quantity is as follows: sulphurous acid, 1¾ g [illegible] a [illegible] r [illegible] and its products, canned and bottled foods, fruits and their products (such as jams, &c.), temperance drinks, fresh fish, pickles, and condiments. It may be mixed in the specified proportion or less with beer in all forms and with flesh foods in general. In a similar way the regulation deals with salicylic acid and with benzoic acid, but the list of excepted foods with which these bodies may not be mixed is more comprehensive. They are forbidden in all the articles mentioned, also in preserved fish, all flesh foods, and in beer, cider, and perry as well. Boric acid is forbidden in milk and in cream intended for use as such, but no reference is made in regard to its use in milk and cream in course of manufacture into butter, and it is permitted in bacon and ham and in preserved fish. Boric acid in butter is allowed in proportions not exceeding 35 grains per pound.

Hospital Affairs.

The annual report of the Children's Hospital, Sydney, presented to the twenty- [illegible] stated that 560 patients [illegible] general hospital and the [illegible] previous year. Of these 394 were discharged cured, 70 were relieved, 35 were unrelieved, and 63 died. There were 177 admitted to the diphtheria hospital and of them 143 were cured and 23 died. The out-patients numbered 3525, whose attendances were 15,638. Compared with the previous year there was an increase of 68 patients treated in the general hospital. The death-rate was 10·4 per cent., as against 11·1 per cent. last year. In the diphtheria branch there was a decrease of 14, while the death-rate was 12·02 per cent., as against 18·8 per cent. in the previous year.—Under instructions from the Victorian Under Treasurer an important circular has been issued to the committees of hospitals throughout the State, pointing out that the only persons eligible for treatment in hospitals subsidised by the State are:—1. Those who are entirely destitute. 2. Those who are unable to pay the ordinary medical fees but who are in a position to contribute towards their maintenance while in the institution. 3. Accident cases, which are always admissible. Under the provisions of the ticket, therefore, no person (except in cases of accident) who is not in a position to sign one or other of the declarations to the ticket must be admitted for treatment. Under the prescribed ticket the committee of management or some officer deputed by it for the purpose is required to examine the circumstances of each applicant for admission and, where necessary, to fix the amount of contribution. For the general guidance of the committee of management it is laid down that where it is found that the circumstances of an applicant under the declaration of "ability to contribute" warrant a contribution of more than £1 per week being imposed, special inquiries as to whether such applicant is a suitable object for charity should be instituted and precautions taken that no one who can pay the ordinary medical fees shall be admitted for treatment.—During a terrific storm at Townsville, Queensland, the hospital was seriously wrecked. Mr. W. R. Bacot succeeded in removing most of the patients, but five were killed and three persons were seriously injured, including a nurse.

Unregistered Practitioner Fined.

At the Newtown police-court A. M. Keighley was charged with using words implying that he was a legally qualified medical practitioner. The defendant stated that he held a diploma (produced) from the College of Ohio which entitled him to practise in any part of America. In September, 1899, at the court of quarter sessions at Newcastle he was called as an expert medical witness on behalf of the Crown. He had seen the diploma of Charles Ebden Crommelin referred to in a copy of the Register. It was issued by the same College. Defendant said he went through the Cincinnati

College of Medicine for a regular course and was duly examined and upon that examination he got the diploma. He was gazetted in the *Cincinnati Times*. Previously to that he studied for nine months at the London Hospital School of Medicine and was for 15 months at the Hospice du Sacré Cœur in France and was also for 12 months in a hospital at Bombay. He served six and a half years in broken periods in the study of medicine before receiving the diploma. On Jan. 11th, 1901, he was charged at the Lambton police-court with a breach of the Medical Practitioners Act and was fined £50, but it was afterwards reduced to £10. He had made applications for registration in 1901 and 1902 which were refused. Having given some details of his medical studies the defendant said that at the second trial at Maitland in 1901 he produced the diploma and the jury acquitted him. In reply to the bench he said that the diploma was not in the same state now as when he received it. He had had it framed and the seals had been eaten by silver fish. There had been lettering on the seals. The magistrate was not satisfied that the defendant was entitled to be registered and inflicted a fine of £50 or in default four months' hard labour.

United Friendly Societies' Dispensary, Sydney.

The new buildings for the Sydney United Friendly Societies' Dispensary were officially opened by the Premier on March 11th. The building is of brick, three storeys high, and cost about £2000. Some time ago the societies were compelled by the rapid growth of the work to seek fresh quarters. Parliament voted £1000 to assist in the purchase of a site and the societies interested took up debentures for nearly the whole of the balance, the institute paying interest at the rate of 6 per cent. There are branches of the institution at Woollahra and Redfern. As showing the work done it may be mentioned that there are 110 lodges interested in the institute, which dispenses for 9450 members and their wives and families, and that often 500 prescriptions are dispensed in one day.

Action against a Medical Man; alleged Negligence.

An action was brought against Dr. L. G. Davidson of Balmain in the Sydney District Court on March 24th. Damages were laid at £100. The plaintiff, an old lady who had a wound on the side of her head, complained that she had been improperly treated by medicines containing mercury. The jury returned a verdict in favour of the defendant.

April 11th.

Medical News.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations and conformed to the by-laws have been admitted Members of the College:—

Edgar William Allin, M.D., C.M. Trinity, Toronto, Trinity Medical College, Toronto; John James Armitage, St. Thomas's Hospital; George Ernest Aubrey and Thomas Paul Baldwin, St. Bartholomew's Hospital; James Hamilton Hall Baillie, M.B., Ch.B., B.Sc., New Zealand, Otago University, and University College Hospital; William Bain, Middlesex Hospital; Henry Edgar Barnes, St. Mary's Hospital; Matthew Robert Blake, M.D., C.M. Trinity, Toronto, Trinity Medical College, Toronto; James Landells Blakie, Otago University and Middlesex Hospital; Hugh Frank Bodvel-Roberts, M.A. Camb., L.S.A. Lond., Cambridge University and St. Bartholomew's Hospital; Lawrence Twemlow Booth, University College and Royal Infirmary, Liverpool; William Braddock, L.D.S. Eng., Owens College and Royal Infirmary, Manchester; John Dell Bridger, Guy's Hospital; Guy Leslie Buckeridge, Oxford University and Guy's Hospital; Richard Burges, Harold Lynch Burgess, and Hugh Rose Cran, London Hospital; Dudley William Carmalt-Jones, B.A. Oxon., Oxford University and St. Mary's Hospital; William Brown Clark, King's College Hospital; Arthur Frederick Cole and George Rowland Henderson Crozier, St. Mary's Hospital; Clement Harlow Cox, Universi[illegible] [illegible]lliam Bayly Crowfoot, B.A. Camb., Cambrid[illegible] Bartholomew's Hospital; Sydney Nelson [illegible] Hospital; Charles Henry Dawe and John Freeman Douse, Guy's Hospital; Charles Frederick Day, Charing Cross Hospital; William Frank Lydstone Day, B.A. Camb., Cambridge [illegible] Hospital; Oscar Chipman Dorman, [illegible] ity College, Dalhousie, and Middlesex [illegible] De Souza, B.Sc Lond., and Frank Rowe Edmonds, University College Hospital; Ernest Alfred Ellis, B.A. Camb., Cambridge University and London Hospital; Rowly Steavens Wykeham FitzHenry and Peter Gifford Foulkes, Middlesex Hospital; Henry Harper Formby, M.B., B.S. Melb., Adelaide and Melbourne Universities and London Hospital; John William Fox, Sheffield Medical School and London Hospital; William Edmund Gibson, M.B., Ch.B. New Zealand, Otago University and University College Hospital; Ellis Gordon Goldie and Herbert Myer Goldstein, Guy's Hospital; John Leopold Goldstein and Edward Michael William Hearn, London Hospital; William Haywood Hamilton, Reginald Janson Hanbury, and William Charles Frederick Harland, St. Bartholomew's Hospital; Horace Guy Lankester Haynes, Cambridge University and Westminster Hospital; James Willie Heslop, M.B., B.S. Durh., Durham University; James Howard, Owens [illegible] [illegible]rmary, Manchester; Bernard Hudson, M.A. C[illegible] niversity and St. Bartholomew's Hospita[illegible], Sheffield Medical School and St. Thomas's Hospital; Charles Wilmot Wanklyn James, General [illegible] St. Mary's Hospital; Henry Walter James, [illegible] ardiff, and St. Bartholomew's Hospital; [illegible], London Hospital; Smeeton Johnson and Seymour Whitworth Jones, St. Mary's Hospital; Hector Jones, University College, Cardiff, and St. Mary's Hospital; Charles Russell Keed, Henry Arthur Kellond-Knight, and Charles Samuel Kingston, St. Bartholomew's Hospital; Francis Seymour Kidd, B.A. Camb., Cambridge University and London Hospital; Charles James Izzard Krumbholz, M.B. Lond., University College Hospital; Cecil Lionel Lakin, Charing Cross Hospital; Percival Wilson Leathart, B.A. Camb., Cambridge University and St. Bartholomew's Hospital; Austin Clement Le Rossignol, B.A. Oxon., Oxford University and London Hospital; Eric Craigie Lindsey and Hugh Marcus Major, St. Mary's Hospital; Harry Bertram McCaskie, B.A. Camb., Cambridge University and St. George's Hospital; John Crichton Stuart McDouall, Otago University and University College Hospital; Stuart Donald Mackenzie, M.D., C.M. McGill, McGill College, Montreal; Harold Charles Cory Mann and Gordon Moir, Guy's Hospital; Edward Henry Milner-Moore, St. Mary's Hospital; Harold Joseph Moon, Owens College and Royal Infirmary, Manchester; Clifford Arthur Moore, General Infirmary, Bristol; James Cecil Mottram, University College Hospital; Percy Knowles Muspratt, Cambridge University and London Hospital; Clive Newland, M.B., B.S. Adelaide, Adelaide University and London Hospital; Wilfred Cowan Nimmo, Westminster Hospital; John Howard Le Bouverie Page, St. Mary's Hospital; Philip Noel Panton, B.A. Camb., and Henry Irving Pinches, B.A. Camb., Cambridge University and St. Thomas's Hospital; Frederick Samuel Pope, M.D. Toronto, Trinity Medical College, Toronto, and University College Hospital; Frank Gray Quinby, L.D.S. Eng., University College, Liverpool; John Douglas Pearson, Walter Woolfe Read, Ernest Roberts, and Frederic[illegible] Hospital; Bakhshi Isaac Raham, King's [illegible] spital; Harold Rischbieth, M.A. Camb., [illegible] and London Hospital; Harold Joseph [illegible] Cambridge University and St. Thomas's Hospital; Charles Russ, St. Mary's Hospital; John Noel Sergeant and Frederick William Weeks Smith, St. Thomas's Hospital; Hugh Hamilton Serpell, St. Bartholomew's Hospital; Charles Robert Shattock, L.D.S. Eng., King's College and Guy's Hospital; John Godfrey Slade, M.A. Camb., Cambridge University and St. Bartholomew's Hospital; William Clayton Smales, King's College Hospital; Malcolm William Stewart Smith, University College Hospital; Charles Sigismund Stolterfoth, University College and Royal Infirmary, Liverpool; Francis Talbot, Charing Cross Hospital; Harold Theodore Thompson, M.A. Camb., B.Sc. Lond., Cambridge University and London Hospital; Hugh Watts, St. George's and Guy's Hospitals; Ernest Weatherhead, Cambridge University and London Hospital; Bernard Harry Wedd and Harold Charles Winckworth, Guy's Hospital; Edmund George Harrison Weir, M.D., C.M. Toronto, Trinity Medical College, Toronto, and Middlesex Hospital; George Sydney Welham, Charing-Cross Hospital; Edward Aubrey Guy Wilkinson, B.A. Oxon., Oxford University and St. George's Hospital; Frederick Whitaker, B.A. Camb., and Henry Lydiard Wilson, B.A. Camb., Cambridge University and St. Bartholomew's Hospital.

UNIVERSITY OF CAMBRIDGE.—The following medical and surgical degrees were conferred on May 14th:—

Doctor of Medicine.—D. G. Hall, Emmanuel.

Bachelor of Medicine.—W. D. Chapman, Corpus; and A. E. Hodder, King's.

Bachelor of Surgery.—W. D. Chapman, Corpus; T. Guthrie and G. R. Rickett, King's; F. W. Goyder, St. John's; W. T. Scott, Clare; H. Ackroyd, Gonville and Caius; G. A. Wright, Christ's; J. M. Stenhouse, Sidney-Sussex; and E. A. Ellis, Downing.

The last stone of the new Humphry Museum has just been laid and the Downing-street portion of the new medical school building is ready to receive its fittings. For these a sum of some £8000 is still required. It is hoped that the laboratories and lecture-rooms will be ready for occupation during the summer.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following candidates have passed the Primary part of the examination for the Licence in Dental Surgery of the College:—

T. Flanagan, H. D. Griffith, J. W. Harvey, and W. Ogilvy.

UNIVERSITY OF DUBLIN: TRINITY COLLEGE.—At examinations held at Trinity term the following candidates were successful:—

Previous Medical Examination: Anatomy and Institutes of Medicine.—William F. Samuels, Charles E. C. Williams, and Henry H. White.

Physics and Chemistry.—Thomas Creaser and William J. Thompson.

Botany and Zoology.—Maurice Fitz Gibbon, Herbert Wright, Thomas W. E. Henry, John W. Lane, William J. Thompson, Charles B. Jones, and Cecil R. W. Stoney.

FOREIGN UNIVERSITY INTELLIGENCE —*Berlin.* Dr Paul Lazarus has been recognised as *privat docent* of Medicine and Dr Kurt Stranch as *privat docent* of Forensic Medicine —*Bonn* Dr Rosemann of Greifswald has been appointed to the Physiological Institute to replace Dr Bleibtreu who goes to Greifswald —*Budapest* Dr Michael Mohr has been recognised as *privat docent* of Pediatry —*Cadiz* Dr Leonardo Rodrigo Lavin has been appointed Professor of Physiology —*Gratz* Dr Theodor Muller has been recognised as *privat docent* of Hygiene —*Leipsic* Dr von Criegern has been recognised as *privat docent* of Medicine —*Malta* Dr Carmelo Mifsud has been appointed Professor of Medicine in succession to Dr Galea who has resigned —*Vienna* During the building of the new hygiene institute the lectures are being delivered by Dr Schattenfroh, extraordinary professor It is expected that Professor Flugge of Breslau will be appointed to the chair of Hygiene when the institute is finished, which will not be until next year —*Wurzburg* Dr Johannes Sobotta *privat docent* of Anatomy, and Dr Johannes Muller, *privat docent* of Medicine, have been promoted to Extraordinary Professorships

THE MEDICAL GOLF TOURNAMENT —The annual medical golf tournament will be held on Thursday, May 28th, on the links of the Hanger Hill Golf Club at Ealing by kind permission of the committee of that club The tournament will be under the same rules as last year—viz, 18 holes, match play, *v* Bogey in the usual two handicap classes, (1) 12 and under, (2) over 12 Members of the Hanger Hill Golf Club will deduct two from their handicap and no match can start after 3 P M There will be a foursome sweepstake *v* Bogey in the afternoon Players arrange their own matches or can apply for a partner to the honorary secretary Entries, stating lowest handicap and inclosing 5*s* entrance fee, to be made by May 26th to the honorary secretary, Mr Rolf Creasy, Windlesham, Surrey

UNIVERSITY COLLEGE, LONDON —At the session of the council of University College on May 4th the Liston gold medal for clinical surgery was awarded to Mr G E O Williams Mr Bilton Pollard was appointed additional examiner for the Atkinson Morley scholarship Dr W H Corfield was appointed a delegate to represent University College at the Liverpool Congress of Public Health In consequence of ill health Dr G V Poore has found it necessary to resign his chair of Medicine and Clinical Medicine and his physicianship to University College Hospital The council in accepting the resignation, unanimously adopted a resolution testifying to its high appreciation of the services which Dr Poore had rendered to the college and hospital during the past 35 years and especially expressing its great obligation to him for the active part which he took in bringing about the rebuilding of the hospital and in preparing the design for the new building

ASYLUM WORKERS' ASSOCIATION —At the annual meeting of this association held on May 14th at 11, Chandos street London, W, Sir James Crichton Browne the President, being in the chair, the report for the year 1902 was presented by the honorary secretary (Dr G E Shuttleworth) and its adoption was moved by the chairman in an interesting address He stated that the association had increased its membership to 4902 and he trusted that 5000 might henceforth be regarded as its minimum strength With reference to lunacy legislation the executive committee had urged on the powers that be the claim of the public asylum service to adequate and assured pensions, not only in the interests of officials but of the patients themselves whose welfare very largely depended upon the efficiency and stability of the service The "Homes of Rest' fund had done good work in helping sick and weary workers to recuperate, and the institution of prizes for the study of standard works of fiction (in which Mr Rider Haggard had kindly promised personal support) helped to create interests outside their sometimes depressing duties Medals had been granted for long and meritorious service in asylum nursing and this year the two gold medals (for more than 35 years' service) had been awarded to Mr C H Marshall of the Eastern Counties Asylum and Miss M A. Buckle of the East Sussex Asylum and the two silver medals (for more than 30 years service) to Mr J Lynch of the Cork District Asylum and Miss A E Jackson of Bethlem Royal Hospital A memorial brass had been provided for Colney Hatch Asylum to commemorate the heroic conduct of the staff on the occasion of the recent calamitous fire

VACCINATION GRANT —Mr George Fisher, M R C S Eng, who has received the vaccination grant for the fourteenth consecutive time in the No 6 "Albury District of the Guildford Union," was appointed public vaccinator on April 11th, 1874

MEDICAL HIGH CONSTABLE —Mr Cornelius Biddle, L R C P. Lond, M R C S Eng, at the unanimous request of the Merthyr Tydvil bench of magistrates, has decided to hold the office of high constable for Caerphilly Higher for another year

"The Londoners" Amateur Operatic and Dramatic Society, of which Sir Frederick Bridge, M V O, is President, will give four performances of the successful musical comedy *Florodora* at the Great Queen street Theatre, London, W C (by kind permission of Mr W S Penley), on Thursday and Friday, May 28th and 29th, at 8 P M, and on Saturday, May 30th, at 2.30 P M and 8 P M, in aid of Pearson's Fresh Air Fund The honorary acting and business manager is Mr Townley Searle who writes from the theatre and from whom tickets may be obtained He states that there are no expenses of management and that every penny is spent on the children

THE LONDON HOSPITAL QUINQUENNIAL APPEAL —At a meeting held at the Poplar Town Hall, under the presidency of the Mayor of Poplar, on May 14th, in support of the London Hospital Quinquennial Appeal, the Hon Sydney Holland in the course of an address, said that it required £300 a day to carry on the work of the London Hospital. It was sad, he said, to contemplate that the working classes of London displayed a great want of interest in hospitals and contributed to hospital charities less than did the workmen of any other town If such an institution as the London Hospital failed it would be difficult to estimate the resulting misery

Parliamentary Intelligence.

HOUSE OF COMMONS

THURSDAY, MAY 14TH

Escape from a Small pox Hospital

Mr WEIR asked the President of the Local Government Board if he would state in what circumstances a man named Costello of Latimer street Liverpool, recently escaped from Fazakerley Small pox [illegible] to the grounds of the hospital [illegible] not propose to take any steps in the matter

Overcrowding in Liverpool

Mr WEIR [illegible] whether he was [illegible] Liverpool 11 [illegible] overcrowded [illegible] were visited [illegible] former house [illegible] number while at the latter [illegible] that the houses are the property of the corporation of Liverpool whether [illegible] registered for the accommodation of emigrants None of these are in the possession of the corporation It is stated that the houses are of a high class of respectability and that the emigrants using them are chiefly Scandinavians who are cleanly and well-conducted people The houses are stated to be kept scrupulously clean They are under the supervision of the corporation and are visited daily and frequently by night also The unexpected arrival of a large body of emigrants on March 24th resulted in an excessive number being received in Nos 11 and 12. Proceedings were taken by the corporation in respect of the overcrowding thus caused and a fine was imposed in each case As regards small pox I am assured that the disease is very rarely introduced into Liverpool by emigrants who as a rule are vaccinated before starting I am glad to add that the outbreak at Liverpool is stated to be subsiding a result which appears to be largely owing to the strenuous action taken by the corporation

Medical Officers of Militia and Volunteers

Major RASCH asked the Secretary of State for War if he would explain why those medical officers of the Militia and Volunteers whom the War Office had employed continuously for the last three years or more in lieu of Royal Army Medical Corps officers, and whose services it still found necessary, through the dearth of regular medical officers, to retain for the same duties, no longer receive the pay and allowances of their corresponding army rank but have been reduced to a salary of £270 per annum, a reduction in the case of a lieutenant of more than £50, and in that of a captain of nearly £100 per annum.—Mr. BRODRICK replied: These officers have been demobilised and are now employed as civil medical practitioners. They act as such entirely at their option and it is impossible to treat them differently from other civil medical practitioners.

MONDAY, MAY 18TH.

The Contamination of Oyster Beds.

Mr. SEYMOUR ORMSBY-GORE asked the President of the Board of Trade if in view of the cases of typhoid fever caused by oysters reared in insanitary beds, he would consider the advisability of appointing an inspector of oyster beds.—Mr. GERALD BALFOUR replied: The question of preventing the spread of typhoid fever is primarily one for the sanitary authorities, and I do not think that the appointment of a special inspector of oyster beds by the Board of Trade is necessary. I may, however, mention that the Board of Trade is considering with the Local Government Board whether in particular cases joint action might not be taken by the local sanitary and fishery authorities with a view of preventing the discharge of sewage in the neighbourhood of oyster beds, or where that is impossible of inducing the owners to move the oysters to another site.

Tampering with Whisky and Brandy.

Sir EDWARD STRACHEY asked the Chancellor of the Exchequer whether he was aware that German spirit made from potatoes and roots was imported into this country and sold as Scotch or Irish whisky and that under the existing methods of supervision any potable spirit, German or otherwise, could be made up and sold as genuine whisky; and that English spirit made largely from molasses was shipped from this country to France and returned and sold as brandy; and if so whether he would consider the advisability of appointing a committee of inquiry into the matter.—Mr. RITCHIE replied: I am aware that allegations in the sense indicated have been made, but I have no official knowledge that would enable me to confirm or to refute such allegations. The matter was very fully examined by the Select Committee of the House of Commons in 1890 and I doubt whether any advantage would result from a fresh inquiry.

Cost of Public Vaccination.

Sir THOMAS ROE asked the President of the Local Government Board if he would cause a return to be issued showing the total cost of public vaccination charged on the poor-rate for England and Wales for the two periods of four years—viz., 1895 to 1898 and 1899 to 1902.—Mr. LONG replied: The particulars referred to are shown in Part I. of the Local Taxation Returns which are published annually. The returns for the year ended Lady Day, 1902, are in preparation, and Part I. will, I hope, shortly be ready for issue. It does not seem necessary that a special return should be granted.

Scarlet Fever at the Duke of York's School.

Mr. THOMSON asked the Secretary of State for War whether, in view of the fact that the epidemic of scarlet fever at the Duke of York's School still continued and that the sanitary authority of the borough of Chelsea, although it had been called upon to remove and to disinfect bedding and clothes, had been refused information on the extent of the epidemic and not allowed to enter the school, he would instruct the officials of the school to give entrance to the representatives of the sanitary authority of the borough.—Mr. BRODRICK replied: Nothing is known of any such refusal to give information to the sanitary authorities of the borough. On the contrary the medical officer of the school has been working in cooperation with the borough medical officer of health. It has been decided to remove all the boys who are free from infection and to encamp them for a time.

WEDNESDAY, MAY 20TH.

Infectious Hospital in Conway.

Mr. HERBERT ROBERTS asked the President of the Local Government Board whether his attention had been called to the proposed erection by the Conway rural district council of an infectious diseases hospital on a site abutting on the main road from Llandudno and Colwyn Bay up the Vale of Conway to Llanrwst; and whether, in view of the traffic along the road in question and having regard to public safety, the Local Government Board would take steps to induce the Conway guardians to adopt a more suitable site.—Mr. GRANT LAWSON, who replied, said: I have made some inquiry on this subject and I am informed that the rural district council proposes to erect an infectious hospital at Glan Conway. It is stated that the site, which has been approved by the medical officer of health, is as near the centre of the district as possible and that it would not involve any patient being taken through any town or populous part in going to the hospital. I am also informed that the main road referred to in the question has less traffic than the other main roads in the district. It is further stated that there are no farms or dwelling houses in close proximity to the site and that the hospital would not in any way be detrimental to the interests of the district. It does not appear whether it is intended to borrow money in connexion with the proposed hospital but if it is my sanction will be necessary and before giving it I should cause a local inquiry to be held.

BOOKS, ETC., RECEIVED.

ARNOLD, EDWARD, 37, Bedford-street, W.C.

A Class-book of Botany. By G. P. Mudge, A.R.C.Sc. Lond., F.Z.S., Lecturer on Botany and Zoology at the London School of Medicine for Women (University of London), W.C., and Arthur J. Maslen, F.L.S., Lecturer on Botany at the Woolwich Polytechnic. Price 7*s.* 6*d.*

CARRUTHERS.—On May 13th, the wife of S. W. Carruthers, M.D. Edin., of a daughter.

CAZALET.—On May 17th, at Sutton, Surrey, the wife of Grenville William Cazalet, L.R.C.P. Lond., M.R.C.S., of a son.

FINLEY.—On May 12th, at West Malvern, the wife of Harry Finley, M.D. Lond., of a son.

GLOVER.—On May 14th, at 17, Belsize park, N.W., the wife of Lewis G. Glover, M.D., of a daughter, who only survived her birth a short time.

DEATH.

SKINNER.—On May [illegible]th, at Dyne road, Brondesbury, N.W., David Shorter Skinner, M.D. Brux., Medical Officer of Health for Willesden, aged 67 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

FRIENDLY SOCIETIES AND THE MEDICAL AID QUESTION.

UNDER this heading we read an account in the *Heanor Observer* of May 15th of a meeting which recently took place at Heanor and which was addressed by a Mr. W. Turton. Mr. Turton's address was the usual kind of thing, urging upon the pious members of friendly societies the necessity of union lest the impious medical men should dare to form a union of their own. We only allude to a rather silly address because of the frank manner in which Mr. Turton states what he considers to be the proper relations between a medical man and his patients. The medical officer of a medical aid association "is allowed no private practice whatever and in cases of neglect complaint is made to the managing committee who deals with it in a much different manner than a complaint against your present lodge surgeon can be dealt with. In one case the medical officer is your servant. In the other case he is your master and you are only a small item in his practice." We trust that no medical man will place himself in the humiliating position which Mr. Turton thinks that he should occupy. We have always asserted that the desire of the medical aid associations was to have their medical attendant as their servant, to cut down his pay, to place him under the orders of a lay committee, and to dismiss him at will. We have read speeches in which this view was contradicted by supporters of the medical aid associations and in which the cordial relations that should exist between the associations and their medical men were much insisted upon. We never believed in these cordial relations nor does Mr. Turton.

RESTRICTION ON HOSPITAL RESIDENTS STARTING IN PRACTICE.

To the Editors of THE LANCET.

SIRS,—May I request readers of THE LANCET kindly to let me know the names of towns where hospital residents are appointed subject to the condition that they shall not start in practice before the lapse of a certain time? I believe that there are a good many. Letters addressed to me, care of THE LANCET, will be gratefully acknowledged by me.

I am, Sirs, yours faithfully,

May 20th, 1903. X. Y.

DISTINCTIVE MARKS FOR MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—Some time ago a suggestion was made that medical men should wear some distinguishing style of dress or badge to signify their public calling. As this has fallen flat, so far as I know, I beg to re-direct attention to the subject. In the interest of the public it is often important that a medical man should be recognised by strangers. To give an illustration. A short while since an accident occurred in one of the Midland towns. A crowd, of course, quickly gathered and amongst them an unostentatious but noted surgeon who, on seeing a well-dressed gentleman in a frock-coat and silk hat rush up and take charge of the injured man, withdrew, leaving the case—as he supposed—in the hands of a fellow medico. But it was not so. When the patient rallied the policeman tried to obtain a fee from the friends for the supposed medical man and was considerably taken aback on asking his name to receive the business card of a traveller for a commercial firm. The traveller told me that he felt in great trepidation as to the results of his treatment and the police and crowd were deceived in supposing that a responsible person had taken charge of the case.

I would suggest an enamelled badge bearing a cross, varied according to the branch of work of the wearer—e.g., a gold cross on a blue or red field for a consulting physician or surgeon and a white cross on a blue and red ground for a general practitioner, with a rose, thistle, or shamrock to designate the place of registration. I inclose some designs in explanation. I am, Sirs, yours faithfully,

May 16th, 1903. SIMPLEX.

*** Our correspondent incloses some designs, drawn on heraldic model, for badges to be worn presumably on the watch chain. The devices are ingenious, for anyone knowing the code could detect at a glance the exact degrees or diplomas of the badge-bearer.—ED. L.

SUTURE OF A WOUND OF THE HEART.

A RECENT number of the *Gazzetta degli Ospedali e delle Cliniche* contains an account of a successful case of suture of wound of the heart which was described by Dr. Isnardi at a meeting of the Royal Academy of Medicine of Turin held on Jan. 16th. The patient, a man, 26 years of age, was stabbed in the left side of the chest on Feb. 8th, 1902, and was carried to a hospital in an apparently dying state with the knife still in the wound. On resection of the fourth and fifth ribs the pericardium was found to be punctured and full of blood. The wound in the heart could not be seen on account of the profuse hæmorrhage, but Dr. Isnardi could feel it with his forefinger and under the guidance of this finger he passed a wire suture through its edges. The heart was then gently drawn forward by the free ends of the suture and the hæmorrhage was completely stopped by the application of three sutures. It could then be seen that the wound was in the wall of the right ventricle and was 0 6 inch in length. Empyema afterwards set in, due to the wounding of the left pleura in the course of the operation and another operation had to be performed on this account. For more than a month the heart could be seen beating, both it and the left pleural cavity being exposed. Daily dressings and gauze drainage were employed. The man recovered perfectly and he had been already for some months following his employment as a mason at the time of Dr. Isnardi's communication to the Academy.

A POINT IN THE WORKING OF THE VACCINATION ACT.

To the Editors of THE LANCET.

SIRS,—A curious piece of red tape has come into my experience in the working of the Vaccination Act. Ever since its introduction I have vaccinated all children voluntarily brought to the surgery and charged a fee of 2*s.* 6*d.* in each case. These fees have always been paid till now. Those charged in my last account have been struck out on the ground that I have no claim, but the fees for revaccination at the surgery are still allowed. I could have sent the children home, followed and vaccinated them, and charged a fee of 5*s.*, but this would seem to anyone too grasping and petty in a public officer.

As a sincere admirer of the new system, the working of which I have watched with great satisfaction, I am much exercised as to the reason of my having to forfeit these fees. Is it the intention of the Act to discourage all surgery vaccinations as tending to propagate infection? No other explanation occurs to me. I find that another officer of our board has had a similar experience.—I am, Sirs, yours faithfully,

May 12th, 1903. ASTONISHED VACCINATOR.

◆

M.R.C.S., L.R.C.P., L.S.A.—It is very advisable to make sure that the methods of vaccination adopted are efficient. If our correspondent is certain that he leaves nothing undone, either in the matter of lymph or in the matter of operation, he might complain to the Local Government Board.

A New Englander writes with the cocksureness of complete ignorance. Exhaustive experiments on the lower animals as well as the personal experiences of many observers have shown all theories with regard to the determination of sex of the kind that he would promulgate to be completely fallacious.

W. M.—The instrument in question has not been submitted to medical inspection. The claims made for it in the lay press are obviously ridiculous.

Enquirer should consult a solicitor and show to him copies of all the documents signed with reference to the engagement, especially the bond.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "To THE EDITORS and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession may be sent direct to this office

Lectures original articles and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR AND IF POSSIBLE OF THE ARTICLE SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed 'To the Sub Editor'

Letters relating to the publication sale and advertising departments of THE LANCET *should be addressed "To the Manager'*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices 423 Strand, W C , are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c , should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers by sending their subscriptions direct to THE LANCET Offices will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year ..	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed 'London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates on this or on any other ground should be resisted The Proprietors of THE LANCET have for many years paid and continue to pay, the whole of the heavy cost of postage on overweight foreign issues , and Agents are authorised to collect, and do so collect from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates whatever be the weight of any of the copies so supplied Address—THE MANAGER THE LANCET OFFICES 423, STRAND, LONDON, ENGLAND

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager. Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

Clinical Remarks
ON
THE RESULTS OF OPERATIONS FOR STRANGULATED HERNIA.

Delivered at University College Hospital in March, 1902,

BY ARTHUR E. BARKER, F.R.C.S. ENG.,
PROFESSOR OF SURGERY AT UNIVERSITY COLLEGE AND SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—You are aware that a very careful analysis with separate tables of all the cases admitted into the surgical wards of this hospital is made every year and printed as the "Report of the Surgical Registrar." Being anxious lately to inquire into some matters relating to the mortality from strangulated hernia I have carefully gone through the "Tables" devoted to this subject in the "Reports" for a number of consecutive years up to the end of 1901, collecting and tabulating all the recorded cases of this condition and the results of their treatment in various ways, Mr. W. B. L. Trotter and Mr. T. R. H. Bucknall having kindly furnished me with abstracts of their unpublished reports for the last two years just going to press.[1] The study of this series has been most interesting and instructive. Such [illegible] ses admitted into one [illegible] same conditions and [illegible] inciples offers the best [illegible] *procured. The theories* [illegible] meaning are, of course, a great help to us, but have to be checked by clinical experience lasting over years and gathered with the greatest approach to accuracy from large numbers of cases arranged in a methodical manner as these have been. Had the figures been greater it is possible that in some respects they would have been more instructive; but as it is 406 consecutive cases of strangulated hernia offer a good basis for study. I desire now to lay before you some of the facts and conclusions to be derived from this analysis, only adding that the "Reports" have been drawn up for a long series of years on a carefully thought out and pre-arranged plan by thoroughly competent officers as their special duty, which included a careful abstract of the post-mortem notes in the fatal cases.

The subject is a most important one, for every surgeon, wherever he is placed, is sure to come in contact frequently with such a complaint as hernia, a complaint which is hardly likely to diminish in frequency inasmuch as it depends in a great measure on anatomical defects in the abdominal wall which we cannot prevent in any known way though we may, and do, remedy them by radical cures. If the practice of performing these latter operations in early life becomes more general it may, of course, come to pass that strangulated hernia will decrease in frequency. But it is not impossible, on the other hand, that the condition may become more frequent as the stress and strain of life become more severe in our ever-increasingly crowded communities. Be that as it may, the number of cases operated on for strangulated hernia in this hospital has gone on steadily rising and for the last 10 years the average number has been just twice as great as 20 years ago. This is partly due to the fact which appears in our tables that reduction by taxis is now less frequently resorted to in severe cases than formerly but not entirely.

As to the diminution in the number of cases admitted into the wards for strangulation and there treated by taxis, it may be stated that in the first series of years taken 36 were so treated by taxis, in the second equal number of years 52, in the third only 19, in the fourth only six, and in the last none at all. Of course, other cases of hernia have been treated by taxis in the casualty department but I am referring now to the more severe cases admitted to the wards severity as its dangers are more fully recognised and more intelligent and common-sense measures are adopted to meet them at *an early moment. However, for the present it is* enough to say that this is a common and dangerous condition occurring in all classes and at all ages. As to the last point, a glance at our tables proves it completely; all ages are fully represented. That it is found among all classes every surgeon of experience knows well. And as to its dangers, we are left in no doubt when we take any long series of consecutive cases admitted for the condition into such an institution as this. Many have been relieved in the past, as we have seen, by taxis, but among such the mortality appears to have been high. In the first series of years in our tables in the cases *not* operated on but treated by taxis or other palliative measures in the wards the mortality was 13·8 per cent.; in the second equal series of years it was 13·4 per cent. Indeed, it has been so high (for the reason that the surgeon in doing taxis never knows the condition of the bowel he *is returning into the abdomen)* that some, myself among the number, doubt whether in any given case of strangulated hernia taxis ought ever to be employed *except in the very recent cases and among aged patients in a state of great weakness.* In this conclusion they are influenced in the first place by the acknowledged uncertainty as to the actual state of the bowel which is to be returned and in the second by the equally acknowledged safety nowadays of exposing the gut by opening the sac and examining it before replacing it And, moreover, the possibility of performing a radical cure in such cases as are quite safe to reduce tells in favour of operating in all cases without resorting to taxis except in those conditions occurring recently in very old people.

That it is difficult in many cases of strangulated hernia to determine what amount of damage may be recovered from is well known and is clear from our tables. Numbers of our cases in which at the operation the gut was put back in the belief or hope that it was sound or viable resulted in death from perforation or peritonitis without actual perforation. The same has been true of cases treated by taxis. In other words, the peritoneum has been infected by septic matter traversing the coats of the replaced bowel in a way that does not take place when the coats are sound. The actual duration of the strangulation has been shown to be an unsafe guide as regards the propriety of replacing the loop in the abdomen. Many of the cases in which it was comparatively short have succumbed to peritonitis after reduction while others have recovered when the strangulation has lasted for days One of the most striking cases illustrating this point was that of a recently strangulated femoral hernia in a healthy woman, 33 years of age. It had positively only been down for 18 hours. When I operated the gut looked somewhat suspicious, but I put it back and did a radical cure. Immediate recovery followed, the wound healing by first intention, and the patient left the hospital quite well on the sixteenth day But some weeks later acute obstruction came on and the result was nearly fatal. Again, some months later another similar, but more severe, attack took place I then opened the abdomen and found the knuckle of gut which had been strangled in the centre of a mass of adherent coils matted together. It was badly kinked just as when reduced four months before and was almost ulcerated through. I removed the whole mass of matted coils, equalling 37 inches of small intestine, united the afferent and efferent portion end to end and the patient recovered without a bad symptom. Here the first strangulation had certainly only existed for 18 hours, but I now see that the intestine ought not to have been put back at the time but should have been immediately resected. This is only one out of many cases pointing to the same conclusion.

But leaving quite apart the cases in which taxis has been applied, a glance at any long list of cases which have required operation still shows a very high rate of mortality. And this in spite of all our improvements in surgical theory and procedure. On this point I will ask you to look for a moment at the last consecutive 406 cases of strangulated hernia admitted to our wards up to the end of March, 1903, and there operated on. In the first place, the gross number of deaths (127) in the whole series amounts to 31·2 per cent. This is a very heavy mortality. But in order to see how far our improved methods and the fact that cases are now submitted to operation with less hesitation and therefore earlier than formerly have influenced the results as time went on. I have arranged the cases in equal series of so many years. You will see (Table I.) that in the first the mortality was 53 1 per cent., in the second 35·7 per cent., in the third 29·6 per cent., in the fourth 28·5 per cent., in the fifth 33·7 per cent., and in the sixth 25·0 per cent. From this it would appear that though there have been some improvement on the gross mortality (31·2 per cent.) during the last few years and a considerable gain as contrasting the last five completed years (22·2 per cent.) with the first (53·1 per cent.), still the mortality had remained almost stationary for several years before 1896—i.e., just 30·4 per cent. And yet this period corresponds with the Listerian method of wound treatment in its full if not its highest development which no doubt partly accounts for the improvement. But it may be asked, Are not the cases of strangulated hernia now brought to the hospital at an earlier stage of the complaint than formerly and therefore less liable to suffer from the risks of operation than in previous periods? This is to a certain extent doubtless true. But that they are not yet brought to us early enough is abundantly evident in three ways when we examine the records. In the first place, the number of cases in which the condition of the patient and bowel was so bad as to forbid anything more in the opinion of the surgeon than an artificial anus being made remains almost equal for each of the series of years and was exactly the same for the first and penultimate. I contrast the penultimate with the previous series because in the last years of all analysed enterectomy has begun to take the place of artificial anus. In the next place, since the year 1887, when the first primary enterectomy was done for this condition, the number of enterectomies for each year has remained practically the same until the last three Thirdly, a study of the post-mortem records in our series—i.e., those cases which have died after operation—shows the same dismal story of either perforation after reduction of the bowel or general peritonitis spreading from the reduced gut in nearly all the fatal cases right down to date. Excluding a few cases which died from shock and lung complications this has been the cause of death in the vast majority of the 30·4 per cent. of failures. I show you here an analysis of the causes of death in the cases dying after operation (Table II.). They amount to 127, of which in 13 the cause was not ascertained or given. Of the remaining 114 it will be seen that sloughing of the gut or peritonitis accounted for at least 55, and indeed that about 100 died from trouble depending upon the state of the bowel returned. In other words, if it had been possible to treat these cases without returning the gut there would probably have been a much lower death-rate.

---

[1] Since these remarks were put together Mr. Trotter has further favoured me with the figures for 1902 and to the end of March, 1903, which have here been incorporated with the original tables.

TABLE I.—*Consecutive Series of Cases of Strangulated Hernia Operated on up to the End of 1901.*

First series of years, mortality	53·1 per cent.
Second " " "	35·7 "
Third " " "	29·6 "
Fourth " " "	28·5 "
Fifth " " "	33·7 "
Sixth " " "	25·0 "
406 cases, gross mortality	31·2 "
Last series	22·2 "

Collapse...	17	Lung embolism	2
Asthenia	14		114
Lung troubles	16	Unascertained	13
Heart failure...	2	Total	127

This being so, it is only natural to inquire whether this high mortality of from 25 to 30 per cent. due to infection of the peritoneum from the returned gut, perforated or unperforated, could not be reduced in some way. Now it is perfectly plain that in the first place this ought to be done by abstaining from replacing the damaged gut within the abdomen in bad cases. This involves either the fixing and opening of the damaged bowel in a surface wound and the establishment of an artificial anus to be closed later if the patient survive or the immediate removal of the damaged loop and anastomosis of the ends thus left. But as to the first means of avoiding reduction of the damaged gut within the abdomen it will be seen from our tables that in only two cases in all these years was the formation of an artificial anus successful in averting death, although the character of the cases so treated had not materially altered and the procedures may be assumed to have somewhat improved. Very little then is to be hoped from this procedure unless performed at a much earlier date than hitherto. There remains, then, enterectomy; and by this I mean the primary removal of the damaged loop without the previous formation of an artificial anus. Can we expect to have better results from this procedure than from those in vogue hitherto? Now up to the summer of 1899 no single case of successful enterectomy for this condition, whether primary or secondary, appears in our records. Since then to the end of March, 1903, there have been three cases of artificial anus with two deaths and seven cases of primary enterectomy with four deaths.

This is an important improvement. For from our previous experience I think it may be assumed that every one of these patients recovering after enterectomy would have certainly died, whether the damaged bowel had been simply reduced or had been fixed in the wound and opened so as to form an artificial anus. As to the condition of the gut in each case we can speak with confidence. It was hopelessly damaged. To have put it back would have been to court disaster and to have formed an artificial anus would have almost as certainly led to the same result. There appears, therefore, to be good reason for hoping that in primary enterectomy in selected cases we may in the future have the means of reducing our mortality still further. Of course, cases will still be brought to us in too collapsed a condition to justify the hope that any long operation will save them. But from our records we can see that there are a large number of others admitted in very fair condition in whom after a very simple and rapid operation with reduction death has nevertheless followed from peritonitis with or without perforation, and it is among them that primary enterectomy will play a very beneficent rôle, I believe, in the future. Had it not been for the successful resections of gangrenous gut performed within the last four years the mortality would have been apparently 30 0 per cent. instead of 25·0 per cent. for the last quinquennium, or 24 0 per cent. for the last four years instead of 18·0 per cent. which was actually the case. We want further experience and a larger number of cases to speak positively, but this fact is significant.

But of course the whole question turns to a large extent upon our possessing or not an adequate mastery of the principles which underlie the excision of damaged intestine and confidence in any given case that this operation subjects the patient to a smaller risk than other procedures. For my own part I know of no operation which demands from the surgeon a wider knowledge of the newest pathological lore or a more patient and laborious inquiry into every detail in the methods of carrying it out. But we are improving in both directions and I feel sure that before long we shall attain to such a proficiency as very materially to influence the mortality in the conditions alluded to above and in those allied to them. And if there be any weight in all this reasoning, that in all the cases which die after operations for strangulated hernia more than half are lost because damaged bowel is put back into the abdomen which ought never to have been so reduced, it becomes our duty very carefully to study the principles which underlie the procedure of removing at once the gangrenous loop and also the many details which in the course of time have come to be considered indispensable. This is a very wide subject. It involves a study of the whole mechanism of strangulation of gut and then the relation of the latter to the secondary enteritis and peritonitis produced by it and the bacterial infection consequent on it. It also requires a careful consideration of the processes of repair in intestinal wounds. Finally, a survey of the mere mechanism of removal of the damaged coil and restoration of the continuity of its tube must be made minutely. All this takes us very far afield. The details which have been found necessary to insure success appear almost endless and yet they must be understood and mastered if we are to be successful. Now one of the most important steps we can take in such a study is to examine closely into the causes of death in those cases of enterectomy for one or other condition which have been unsuccessful in saving life, whether among our own or outside records. Here we shall find much to instruct us in the first place as to the selection of cases in which such a procedure is demanded and is not too late, next as to the length of the portion of intestine to be resected, and finally as to the conditions which must be observed in uniting the cut ends. This would, however, lead me too far to-day. I will only remark in conclusion that errors in technique are becoming rarer and, as was pointed out to me by our surgical registrar, the last unsuccessful cases of enterectomy show in the post-mortem records that death in each was due to causes quite independent of the details of the procedure and was really consequent on the general condition of the patient at the time of the operation. One was due to a band of old fibrous tissue which caused a second strangulation when the junction after resection had been made successfully.

A Clinical Lecture

ON

ACHOLIA.

Delivered at St. Mary's Hospital Medical School on May 7th, 1903,

BY W. B. CHEADLE, M.D. CANTAB., F.R.C.P.,

SENIOR PHYSICIAN TO ST. MARY'S HOSPITAL AND LECTURER ON CLINICAL MEDICINE AT THE MEDICAL SCHOOL; CONSULTING PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

GENTLEMEN,—An affection of the digestive tract which has received scanty consideration either from pathologists or clinical observers—although it has not passed altogether unnoticed—is that condition which I have ventured to term "acholia." In its minor degree it is by no means very uncommon; you may have seen a mild but not uncomplicated case of the kind in a child a few weeks ago in De Hirsch ward. In its more extreme and rarer forms it is a serious disorder and sometimes, although rarely, of fatal issue. I have seen one fatal case only.

Acholia is specially characterised, as the name implies, by the absence of bile in the stools—without jaundice or sign of obstruction to the biliary outflow from the ducts. This peculiar condition of the stools without jaundice has been noted by clinical observers in varying circumstances and in different disorders without in most cases any special appreciation of its pathological significance. One form of it in children has been described by that acute clinical observer, Dr. S. J. Gee, in 1888, under the name of cœliac disease[1] or belly affection, from κοιλία, the belly, in allusion to the flaccid distended abdomen and implication of the abdominal organs, and he gives an excellent clinical presentation of the disorder in all its symptoms, designating it as a form of chronic indigestion. Cases of the same nature have been recorded by Dr. R. A. Gibbons[2] in a thoughtful and suggestive article published in the *Edinburgh Medical Journal* 11 years later, in which he expresses the opinion that the source of trouble will be found in the liver. Similar conditions of the stools in the case of adults have been noted by Sir Joseph Fayrer in the so-called white diarrhœa of the tropics and by Dr. P. Manson and Dr. G. Thin in sprue. A condition of colourless stools has also been described by Dr. T. J. Walker of Peterborough in an interesting paper published in the Transactions of the Royal Medical and Chirurgical Society for 1889, as occurring in two cases of complete obstruction of the pancreatic duct. In one instance these colourless stools persisted uninterruptedly for a period of upwards of 20 years. Dr. Gee's cases and those of Dr. Gibbons occurred in children, but those described by Dr. Walker occurred in adults upwards of 50 years of age and the white diarrhœa and sprue of the tropics are met with chiefly in grown persons.

The term "acholia," which I have been in the habit of using to indicate this condition of abilious stools, has also, I find, been adopted by Dr. Manson to indicate the same phenomenon in the case of sprue. It is terse and emphasises the chief and most striking feature of the affection—viz., the absence of bile. This obvious and distinctive symptom of the disease varies somewhat in degree. In some cases the fæces are merely pale, fawn colour, or straw colour, in others clay-coloured only, like putty, but in more extreme and typical cases they are absolutely white, without a vestige of colour except a slight tint of grey—as white as pipeclay or white paint. Now, you are no doubt familiar enough with this absence of colour in the fæces—clay-coloured or white evacuations—in the case of jaundice. In this condition the bile does not pass into the duodenum; unable to escape out of the hepatic duct or common duct on account of closure or obstruction of the pipe the contents of the bowel are not coloured by it, and remain clay-coloured or white. The bile, held back in the liver and its ducts, is absorbed into the blood, the urine is charged with it, it stains all the tissues, and jaundice results. The pathology of the condition of white stools in jaundice as a consequence of obstruction to the outflow of bile is of course simple and intelligible. In acholia, however, there is no jaundice; the stools are as white as those of obstructive jaundice when bile is absolutely shut out from the intestine, but there is no resorption of bile into the blood, or if there is it must be quickly destroyed there, for there is no staining of the tissues by its colouring matter; it does not appear in the urine. Bile is clearly not pent up in the liver or it would be reabsorbed and its pigment would enter the circulation and appear in the urine and in the tissues as in ordinary obstructive jaundice.

Let us look more precisely into the conditions under which these colourless stools without jaundice are met with. In the first place, white stools of this character occur not infrequently in persons who live highly—in the matter of food and drink—and in people of gouty habit. Now and again they pass light-coloured whitish stools for a few days, accompanied by malaise, disgust for food, a general sense of being out of sorts, and with this often a yellowness of complexion not amounting usually to actual jaundice. After a cholagogue purgative and restricted diet the motions shortly resume their normal character. I have seen a similar condition arise from time to time in chronic Bright's disease and I imagine that a passing acholia may be more common than is supposed. We examine the urine most religiously, but the state of the fæces, in the case of adults at least, is little observed.

These examples of partial acholia are, however, casual, temporary, and of no importance except as signs of passing liver disorder. But white stools of more persistent character and of more serious import involving danger to nutrition occur also. They are met with in hot climates in fluor albus or white diarrhœa and in sprue, for which the former is probably only another name. In this country, however, acholic stools occur usually in children under five years of age, but by far the most often in the first two years of life. It must be borne in mind that young children who are fed entirely, or chiefly, on milk have naturally light motions, but these have always a distinct yellow or brownish tint, and can be distinguished from those of a true acholia. In a typical acholia the fæces are not merely pale, they are a dirty grey or absolutely white, in well-marked cases without a shade of yellow or brown. They are obviously as destitute of bile as those of complete obstructive jaundice. Usually they are slightly loose, like oatmeal gruel or milk gruel; sometimes, however, they are like a mass of white paste or white paint. And there is the other special feature—viz., that they are distinctly greasy in appearance, glistening, fatty. Another characteristic feature is that the stools are distinctly offensive—often horribly so—stinking. And, lastly, they are larger than normal, more voluminous, as if food taken in was imperfectly absorbed.

The onset of acholia in children is usually abrupt, as in the child mentioned in De Hirsch ward; all at once the colouring matter disappears from the fæces which quickly assume the greyish-white tint and the frothy, greasy, offensive, loose character already described. In other cases the change is more gradual, the stools, which at first are merely pale, becoming less and less coloured until all pigment disappears. The advent of these soft greasy, offensive, voluminous white stools is speedily followed by marked impairment of general health. At first there may be some rise of temperature, especially if dentition is troublesome, but after a time the temperature falls to normal or sub-normal, the appetite fails notably, and the child becomes pallid, languid, and enfeebled. The patient not only ceases to thrive but becomes flabby of flesh, loses weight,

T health with hearty appetite. In addition to full
usi he had massage and galvanism to the abdomen,
drug treatment was limited to bismuth to restrain
e flux and pancreatin in keratin capsules. The object
e keratin covering is, as you know, to protect the
ents from being acted upon by the gastric juice and
insure its passage intact into the duodenum where its
physiological action on food commences. On one or two occasions ox gall was given in this way with the striking result that the fæces, which were very acid, showed now streaks and patches of brilliant grass green colour; the addition of bile to the stools produced biliary colouring, indicating that the absence of this was the cause of the absence of colour. Under this treatment the patient began to gain weight—one pound a week only at first—and a slight brown colouration of the fæces developed; at the end of six months he had practically recovered. The bowel digestion had become normal. His weight had risen to 11 stones.

The preceding case was no doubt one of "sprue"—contracted abroad—in which white loose stools of this character, dry tongue, and progressive emaciation are the main features. I have related it for the sake of comparison with the acholic condition in children. The condition of the stools in the two forms is absolutely identical; some of the symptoms, notably the appetite for food, are different.

With regard to the pathology of these conditions, naturally the first question which arises is whether bile is actually excreted by the liver at all, or whether it is bile pigment only which is wanting, or whether although it is formed it is wholly reabsorbed—not partially only—or so changed in transit that it fails to colour the fæces? An explanation on this latter hypothesis has been put forward by Dr. Walker of Peterborough, based upon the two cases of obstruction to the pancreatic duct before mentioned. Dr. Walker suggests that there is some defect in the transformation of the biliary pigment so that it is not converted into the hydrobilirubin of the fæces; that this transformation is normally effected by the pancreatic secretion and that the absence of this, as in his cases of occlusion of the pancreatic duct, is the cause of the absence of the normal colour.

That the functions of the liver are gravely interfered with, and possibly those of the pancreas also, seems certain from several considerations. 1. The stools are obviously greasy; in some instances you can see fat standing on the surface so thick that they glisten like talc and on analysis are found to contain an enormous excess of fat, from 24 to 63 per cent., the normal being from 11 to 12 per cent.—i.e., twice to more than five times as in the normal state. 2. The stools are acid, or slightly alkaline only, and are extremely offensive, presumably from decomposition of fats owing to the absence of bile, which is known to have antiseptic power[3] and arrests fermentation.[4] 3. The stools are large in volume out of proportion to the food taken, indicating imperfect digestion and absorption. 4. The patient wastes rapidly, and in protracted cases becomes greatly emaciated, white, flabby, and anæmic. 5. In all cases bile pigment is deficient and in extreme and typical cases, where the stools appear white, no trace of it can be found. Moreover, in the most marked cases analysed by Dr. Willcox the bile acids were entirely absent also. In the case of sprue the results of different observers in this respect are contradictory. The effect of the administration of ox gall in producing green colouration of the stools points to the absence of this being the cause of absence of colour. 6. Although the urine has only been fully examined in two cases, in one urea was largely deficient (only 0 45 per cent.) and in another in excess, and crystals of leucin were observed, this being indicative of imperfect liver function.

As far as I know no definite lesion has been discovered post mortem. In the one fatal case which I have met with no post-mortem examination was permitted, but it is stated by Dr. Gibbons that the intestines show no marked change and the only abnormal conditions met with are some enlargement of the spleen and anæmia. The liver, where one would expect the secret might lie hidden, is normal in appearance. In sprue there are extensive necrotic erosion of the mucous lining of the bowel and the stomach is similarly affected. But these, as Dr. Manson observes, are obviously not primary changes, but the result of primary changes, as in starvation, and do not explain the acholia. The pancreas occasionally shows isolated patches of parenchymatous change, but these are not constant. The absence of bile colouring matter and of bile, the quantity of undigested decomposing fat, the wasting (the deficiency of urea and the existence of leucin if confirmed), all point to an arrest more or less complete of the cholagenetic function of the liver, as pointed out by Dr. Manson in sprue, and not merely to an abnormality of bile pigmentation only, and possibly of other intestinal digestive functions also. The explanation given by Dr. Walker of the absence of colour being due to the want of pancreatic secretion essential to its production seems to be negatived in this instance by the fact that the constituents of bile are absent and by the result of the administration of ox bile previously mentioned. This produced brilliant patches of bilirubin in the fæces, showing, I think, that it was the biliary element not the pancreatic that was missing.

---

[3] Tulmann and Gmelin have shown that the fæces become much more fetid after ligature of the common duct.

[4] Carpenter's Physiology.

Causation.—As to the cause—as in sprue—it is most obscure. The frequency with which acholia arises during dentition, especially difficult and painful dentition, the known influence exerted by the nervous system upon gland secretion—as, for example, the effect of stimulation of the chorda tympani upon salivary secretion—the effect of reflex irritation of the spinal cord in lessening the secretion of bile, and, on the other hand, the effect of nervous excitement in producing jaundice, favour the view put forward by Dr. Gibbons that the disease has a nervous origin. It is possibly a dental irritation reflex. We know that this is a cause of diarrhœa and it may be of acholia. The only other condition in addition to teething with which I have noted acholia to be possibly associated is surface chill. It has seemed to me most common in the cold spring east wind time Yet I think the nervous inhibition—a reflex from difficult dentition—is the most probable pathological cause.

Treatment.—The indications for treatment in this affection are to ease the work of the liver, especially with regard to the digestion of fats and starches and to assist its function. To this end fats and starches, and especially fats, should only be given in the raw state in small quantity but chiefly pre-digested, as in pancreatised milk gruel or pancreatic emulsion. For the rest broth, beef tea, fish or meat foods, skim milk, malted bread or biscuit, with the addition of fresh fruit or baked apple for the older children. As for drugs, bismuth and opium if the looseness is troublesome, and those medicines which act as hepatic stimulants and blood stimulants are also useful, together with antiseptics such as salol and listerine. The chlorides of arsenic and iron with perchloride of mercury in small doses have appeared to do good. Brandy in doses of from 10 to 60 drops, according to age, given in a dessertspoonful or tablespoonful of sugar and water, is a useful hepatic stimulant, and if the teeth are pushing and the gums are swollen and painful they should be lanced. Appropriate doses of chloral and bromide—for a young infant from half a grain to a grain of chloral and from three to five grains of bromide of ammonium—are of value as serving to allay reflex nervous irritation.

THE DIFFERENTIATION OF THE CONTINUED AND REMITTENT FEVERS OF THE TROPICS BY THE BLOOD CHANGES.[1]

By LEONARD ROGERS, M.D., M.R.C.P. LOND.,
CAPTAIN I.M.S.; LATELY ACTING PROFESSOR OF PATHOLOGY, MEDICAL COLLEGE, CALCUTTA.

THE great advances which have been made during the last few years in the microscopical methods of diagnosis of malaria and typhoid fever respectively have placed in our hands the power to differentiate, with far greater accuracy than was previously the case, these the most frequently met with and the most important of tropical fevers. Further, by enabling these two to be separated out, we are enabled to investigate, with much greater hope of obtaining at least approximately correct results, the very difficult and all-important question as to whether there are any as yet undifferentiated fevers remaining to be carefully examined and described. The large hospitals of Calcutta furnish an unrivalled field for such an inquiry and, thanks to the great kindness of the medical staffs of these institutions (all of whom are officers of the Indian Medical Service, to whom I desire to express my great obligation), I have been able during the last one and a half years to examine the blood and to carry out the serum tests in about 200 cases of continued and remittent fevers of all kinds, in both the Presidency General Hospital, which admits European patients only, and in the Medical College Hospital, where the majority of the patients are natives of India. The cases have been taken consecutively, as far as possible, every case being examined when time permitted. Further, I have in my possession clinical notes of the cases and four-hour temperature charts, which have been carefully analysed in order to see how far a study of series of different forms of continued and remittent fevers, as proved by the blood and serum examinations, will enable any rules of value to be laid down for their clinical differentiation. The subject is too vast a one to be treated adequately within the limits of a single article, but the principal conclusions which have been arrived at may be set forth and the evidence on which they are based may be summarised.

The nomenclature and classification of tropical fevers adopted by various Indian writers are too varied to be referred to in detail, so it will be best to start with that which Dr. A. Crombie, C.B., laid down in his address in the Medical Section of the Indian Medical Congress of 1894, which may be taken as a valuable summary of what can be said on the subject of the differentiation of Indian fevers, by means of purely clinical methods, by an observant physician of great experience, mostly acquired in the very hospitals in which I have been recently working. In addition to malarial intermittent and remittent fevers, Dr. Crombie in his presidential address in Medicine and Pathology at the Indian Medical Congress in 1894 describes under the head of "continued fevers" three certain and two more doubtful forms, as follows:—1. Simple continued fever, lasting from three to eight days and including three-fourths of the fevers commonly returned under the head of "ague" in India. 2. Typhoid fever, extremely rarely found in natives. 3. "Non-malarial remittent," lasting from three to six weeks, commonly fatal and mostly seen in natives. Doubtful fevers: 4. "Calcutta fever" or "Bombay fever," being an aggravated "simple continued fever," lasting for 14, 21, or 28 days. 5. Low fever, the temperature varying from 99° to 101·5° F., being very persistent, not affected by quinine, but often cured by a complete change.

No. 3 in the above list Dr. Crombie regards as being the most important undifferentiated fever remaining to be thoroughly investigated and its organism identified It was mainly in the hope of separating it, and perhaps other fevers, so as to be able to search for its cause, that the investigation now being described was undertaken. Nearly all the long-continued fevers occurring in the large Medical College Hospital have been examined in the pathological laboratory for a space of 18 months; and at the same time nearly daily visits were made to the General Hospital at the other end of the town for the purpose of examining all similar cases there. In order to simplify matters as much as possible and to avoid repetition, it will be best first to describe my methods and results, and then to compare them with Dr. Crombie's clinical types.

METHODS OF RESEARCH. THE DIFFERENTIAL LEUCOCYTE COUNT.

In addition to the serum tests for typhoid fever and Malta fever and the search for malarial parasites, a new method described by me a year ago[2] has proved to be of the greatest value in this inquiry—namely, the increase in the percentage of lymphocytes in typhoid fever and of the large mononuclear white corpuscles in malarial fevers, by which means alone in the great majority of cases a correct diagnosis can be arrived at by the examination of stained blood films with an ordinary high-power lens. My earlier results have been amply confirmed by the much larger series of cases since examined, while Captain T. H. Delany, I.M.S.,[3] has obtained precisely similar results in upwards of 100 cases examined by him in the Medical College Hospital. The great advantage of this method lies in the fact that the result is in no way interfered with by the previous administration of quinine, as in the search for malarial parasites. As long ago as 1896[4] I showed from an examination of 100 cases of consecutive malarial fever before the administration of quinine that in only one-third of them could the malarial parasite be found by means of a prolonged search of a single blood film; and the absence of the parasite from the peripheral circulation in untreated cases has recently been emphasised by Dr. Stephens and Dr. Christophers.[5] In a still larger proportion of cases which have been treated with quinine will negative results be obtained Thus Maynard,[6] working in the *Calcutta General Hospital* in 1895, found parasites in only 25 7 per cent of 70 cases of malarial fever, nearly one half of which had previously taken quinine *As in my present series quinine had been nearly invariably* given before I was able to examine the blood the search for the parasites was negative in the great majority of *the cases examined* and *no conclusions can be drawn* as to the proportion of malarial fevers in the series from the number in which parasites were found This is also in entire accordance with Captain Delany's[7] recent results for in only 17 per cent of undoubted cases of malarial fever examined by him were parasites found on account of the previous exhibition of quinine while in *over 90 per cent* he was able to *diagnose them correctly* by the large mononuclear leucocyte increase It is worthy of note that Captain Delany and myself, or frequently independently, did counts on the same cases at different times yet never arrived at a different diagnosis The constancy with which a positive Widal reaction for typhoid fever has been accompanied by an absence of any large mononuclear increase, while on the other hand a negative reaction, together with a large mononuclear increase, has been found in nearly all cases which were either obviously malarial *clinically or* which were *subsequently proved to* be so by their reaction to the quinine test in this large series of cases, appears to me to be in itself conclusive as to the great diagnostic value of the leucocyte count Stress is laid on this point at the outset because much of any value in the differentiation and classification of tropical fevers which this paper may possess depends on the correctness or otherwise of this new test, in addition to the serum reaction I have already described the method of counting which I have adopted, so need not repeat it here Briefly, it may be said that blood films were made by spreading out a small drop of blood on a slide by means of the gliding motion of a needle, they were fixed in alcohol and stained by Romanowsky's method Counts were made by working from edge to edge of the middle of the film Mononuclears which were as large as, or larger than the average polynuclears, only were counted as large mononuclears *From 250 to 500 leucocytes* were counted, the smaller number having been found to be quite trustworthy in most cases after some experience

[5] Report of the Malaria Commission of the Royal Society.

The importance of recording the temperature every four hours scarcely needs emphasising, and its value in differentiating between the continued type of many cases of typhoid fever and the severer forms of malarial remittent fever will be dealt with later

TYPHOID FEVER IN EUROPEANS

It will be well to deal with this, the best known continued fever of the tropics, first, so as to be able to have a standard with which others can be compared During the last year an unusually large number of cases of typhoid fever have been admitted to the *European General Hospital* as will be seen from a glance at the upper curve of the appended charts showing the seasonal incidence of fevers so that out of 126 cases of all kinds examir

the past one and a half yea

fever The notes and blood

tabulated in shorthand, so a brief analysis of the most important points regarding them may be given

Age incidence and duration of fever—These are shown in Tables I and II —

TABLE I —*Showing Age Incidence*

Years	5	6-10	11-15	16-20	21 25	26-30	31-40	Over 40	Total
Cases	2	3	11	18	7	6	1	2	50

The percentages in each period can be obtained by doubling the figures given and it will be seen at once that the age distribution of these cases is typically that of typhoid fever

Table II —Showing Duration of Fever

Days	1-7	8-14	15-20	21-25	26-30	31-40	Over 40
Cases	1 (died)	2	8	19	7	6	7

In the very great majority of these cases among Europeans accurate histories can be obtained, so that the accompanying data with regard to the duration of the fever are fairly reliable, although doubtless two or three days at the beginning of some of the milder and shorter cases may have been overlooked by the patients or their relatives In only two cases did the fever last less than 15 days (omitting one case fatal on the fifth day), these being abortive cases which will be referred to again In eight more cases the fever is recorded as having lasted less than 21 days, one of which proved fatal on the seventeenth day Three of them lasted *for 18 days, one for 19 and the other three for 20 days* These were mostly mild cases in which an insidious onset may have been overlooked for a time Of the above cases *lasting less than three weeks all but two were in patients* under 21 years of age typhoid fever being well known to be milder in young persons. Between the periods of from 21 to 25 days, 19 cases or 38 per cent of the whole, fall, while seven cases lasted from 26 to 30 days, six cases from 31 to 40 days and the remaining seven for upwards of 40 days, including four cases in which relapses occurred, the longest *time having been 69 days These figures are also characteristic* of typhoid fever

Clinical characters—With the exception of a few mild cases which did not show very marked symptoms of typhoid fever but were diagnosed by the serum test the series was as a whole typical of the disease and most of them had either been diagnosed as typhoid fever or were suspected to be such before the blood examination was reported In 39 of them looseness of the bowels, with more or less characteristic stools, was noted at some period or other of the fever, while 13 showed constipation *In four hæmorrhage was noted,* in one of which it was attributed to coincident dysentery Characteristic spots were noted in 16 cases, while in 13 they were recorded as having been absent During the hot and rainy season prickly heat is often so extensively present as to make a search for typhoid spots a difficult and uncertain proceeding, but for which they would probably have been found in a larger proportion of cases, for I find that they

months and

Europeans,

the utmost

diagnostic importance as in only eight cases was the abdomen noted as normal and that usually in an early stage of the disease, while in eight more there was no note on the subject, the clinical records having been scanty in some of the milder cases In the remaining 34, or 68 per cent, there was distension, tympanites, or tenderness, or, most frequently, two or more of these symptoms *together were noted The spleen* was felt below the edge of the ribs in only 12 cases and the liver in 16 cases The pulse was frequently noted to be *dicrotic and bronchial* catarrh or congestion of the bases of the lungs also occurred fairly frequently All the above points taken together constitute a *typical* clinical picture of a series of typhoid fever cases which will serve for comparison with other tropical continued and remittent fevers and only the important question of the type of the fever curve remains to be considered under this heading

The temperature curve—The clinical differentiation between a continued and a "remittent type of fever, although simple enough in well marked cases presents difficulties when it is desired to draw a hard and fast line between them As, however, the separation of the continued type, so characteristic of most cases of typhoid fever, from the "remittent' type of severe malarial fevers is of the utmost practical importance an attempt must be made to draw the line somewhere Bearing in mind that the malarial remittent fevers are caused by the malignant tertian parasites, we should expect a marked remission at least every other day in these cases, while any case in which the temperature varied through a range of only two degrees or less for slightly over 48 hours (to allow for some degree of "postponement' in malarial remittent fevers running a favourable course) may be considered to be of a "continued" type The practical value of this definition will appear *presently* and we may now see how frequently this "continued' type occurs in typhoid fever and how early it is present in a characteristic degree An examination of the *four* hour temperature charts of my 50 cases of typhoid fever from this point of view gave the following results. During the first week of the disease there were admitted 29 cases of which 20 were admitted on or before the fifth day and 11 on or before the fourth day leaving three and four days respectively of the first week for observation in hospital yet eight of them showed the 'continued type within that time During the second week 21 more cases showed it and two others during the third week and three at later dates Thus 34 out of the 50 cases presented this feature at some time or other in the course of the disease the great majority of

second week

[7] Brit. Med. Jour March [illegible]th, 1903.

sprue, and not merely to an abnormality of bile pigmentation only, and possibly of other intestinal digestive functions also. The explanation given by Dr. Walker of the absence of colour being due to the want of pancreatic secretion essential to its production seems to be negatived in this instance by the fact that the constituents of bile are absent and by the result of the administration of ox bile previously mentioned. This produced brilliant patches of bilirubin in the fæces, showing, I think, that it was the biliary element not the pancreatic that was missing.

Causation.—As to the cause—as in sprue—it is most obscure. The frequency with which acholia arises during dentition, especially difficult and painful dentition, the known influence exerted by the nervous system upon gland secretion—as, for example, the effect of stimulation of the chorda tympani upon salivary secretion—the effect of reflex irritation of the spinal cord in lessening the secretion of bile, and, on the other hand, the effect of nervous excitement in producing jaundice, favour the view put forward by Dr. Gibbons that the disease has a nervous origin. It is possibly a dental irritation reflex. We know that this is a cause of diarrhœa and it may be of acholia. The only other condition in addition to teething with which I have noted acholia to be possibly associated is surface chill. It has seemed to me most common in the cold spring east wind time Yet I think the nervous inhibition—a reflex from difficult dentition—is the most probable pathological cause.

Treatment.—The indications for treatment in this affection are to ease the work of the liver, especially with regard to the digestion of fats and starches and to assist its function. To this end fats and starches, and especially fats, should only be given in the raw state in small quantity but chiefly pre-digested, as in pancreatised milk gruel or pancreatic emulsion. For the rest broth, beef tea, fish or meat foods, skim milk, malted bread or biscuit, with the addition of fresh fruit or baked apple for the older children. As for drugs, bismuth and opium if the looseness is troublesome, and those medicines which act as hepatic stimulants and blood stimulants are also useful, together with antiseptics such as salol and listerine. The chlorides of arsenic and iron with perchloride of mercury in small doses have appeared to do good. Brandy in doses of from 10 to 60 drops, according to age, given in a dessertspoonful or tablespoonful of sugar and water, is a useful hepatic stimulant, and if the teeth are pushing and the gums are swollen and painful they should be lanced. Appropriate doses of chloral and bromide—for a young infant from half a grain to a grain of chloral and from three to five grains of bromide of ammonium—are of value as serving to allay reflex nervous irritation.

THE DIFFERENTIATION OF THE CONTINUED AND REMITTENT FEVERS OF THE TROPICS BY THE BLOOD CHANGES.[1]

BY LEONARD ROGERS, M.D., M.R.C.P. LOND.,
CAPTAIN I.M.S.; LATELY ACTING PROFESSOR OF PATHOLOGY, MEDICAL COLLEGE, CALCUTTA.

THE great advances which have been made during the last few years in the microscopical methods of diagnosis of malaria and typhoid fever respectively have placed in our hands the power to differentiate, with far greater accuracy than was previously the case, these the most frequently met with and the most important of tropical fevers. Further, by enabling these two to be separated out, we are enabled to investigate, with much greater hope of obtaining at least approximately correct results, the very difficult and all-important question as to whether there are any as yet undifferentiated fevers remaining to be carefully examined and described. The large hospitals of Calcutta furnish an unrivalled field for such an inquiry and, thanks to the great kindness of the medical staffs of these institutions (all of whom are officers of the Indian Medical Service, to whom I desire to express my great obligation), I have been able during the last one and a half years to examine the blood and to carry out the serum tests in about 200 cases of continued and remittent fevers of all kinds, in both the Presidency General Hospital, which admits European patients only, and in the Medical College Hospital, where the majority of the patients are natives of India. The cases have been taken consecutively, as far as possible, every case being examined when time permitted. Further, I have in my possession clinical notes of the cases and four-hour temperature charts, which have been carefully analysed in order to see how far a study of series of different forms of continued and remittent fevers, as proved by the blood and serum examinations, will enable any rules of value to be laid down for their clinical differentiation. The subject is too vast a one to be treated adequately within the limits of a single article, but the principal conclusions which have been arrived at may be set forth and the evidence on which they are based may be summarised.

The nomenclature and classification of tropical fevers adopted by various Indian writers are too varied to be referred to in detail, so it will be best to start with that which Dr. A. Crombie, C.B., laid down in his address in the Medical Section of the Indian Medical Congress of 1894, which may be taken as a valuable summary of what can be said on the subject of the differentiation of Indian fevers, by means of purely clinical methods, by an observant physician of great experience, mostly acquired in the very hospitals in which I have been recently working. In addition to malarial intermittent and remittent fevers, Dr. Crombie in his presidential address in Medicine and Pathology at the Indian Medical Congress in 1894 describes under the head of "continued fevers" three certain and two more doubtful forms, as follows:—1. Simple continued fever, lasting from three to eight days and including three-fourths of the fevers commonly returned under the head of "ague" in India. 2. Typhoid fever, extremely rarely found in natives. 3. "Non-malarial remittent," lasting from three to six weeks, commonly fatal and mostly seen in natives. Doubtful fevers: 4. "Calcutta fever" or "Bombay fever," being an aggravated "simple continued fever," lasting for 14, 21, or 28 days. 5. Low fever, the temperature varying from 99° to 101·5° F., being very persistent, not affected by quinine, but often cured by a complete change.

No. 3 in the above list Dr. Crombie regards as being the most important undifferentiated fever remaining to be thoroughly investigated and its organism identified It was mainly in the hope of separating it, and perhaps other fevers, so as to be able to search for its cause, that the investigation now being described was undertaken. Nearly all the long-continued fevers occurring in the large Medical College Hospital have been examined in the pathological laboratory for a space of 18 months; and at the same time nearly daily visits were made to the General Hospital at the other end of the town for the purpose of examining all similar cases there. In order to simplify matters as much as possible and to avoid repetition, it will be best first to describe my methods and results, and then to compare them with Dr. Crombie's clinical types.

METHODS OF RESEARCH. THE DIFFERENTIAL LEUCOCYTE COUNT.

In addition to the serum tests for typhoid fever and Malta fever and the search for malarial parasites, a new method described by me a year ago[2] has proved to be of the greatest value in this inquiry—namely, the increase in the percentage of lymphocytes in typhoid fever and of the large mononuclear white corpuscles in malarial fevers, by which means alone in the great majority of cases a correct diagnosis can be arrived at by the examination of stained blood films with an ordinary high-power lens. My earlier results have been amply confirmed by the much larger series of cases since examined, while Captain T. H. Delany, I.M.S.,[3] has obtained precisely similar results in upwards of 100 cases examined by him in the Medical College Hospital. The great advantage of this method lies in the fact that the result is in no way interfered with by the previous administration of quinine, as in the search for malarial parasites. As long ago as 1896[4] I showed from an examination of 100 cases of consecutive malarial fever before the administration of quinine that in only one-third of them could the malarial parasite be found by means of a prolonged search of a single blood film; and the absence of the parasite from the peripheral circulation in untreated cases has recently been emphasised by Dr. Stephens and Dr. Christophers.[5] In a still larger proportion of cases which have been treated with st test gave only reactions in the lower dilutions, reacted 1 in 100 at a later date Reactions were obtained some period of the disease in 43 cases, or 86 per cent. ie cases which did not react have been diagnosed as teric fever on account of the clinical evidence of the esence of this disease being very strong and being con med by the leucocyte count to be described immediately will be noted that in the great majority of the cases actions in dilutions of 1 in 40 and upwards were obtained, hich, in my experience are quite conclusive of typhoid ver, although I have twice met with a reaction in a dilution 1 in 40 one and two years respectively after a previous tack, but never up to 1 in 100 except during concurrent phoid fever The occasional absence of a reaction in cases typhoid fever is an experience common to various observers, it I have not had any opportunity of making bacteriological aminations for the presence of the group of bacilli which ive been found in the so called paratyphoid fevers in merica recently, so I cannot say if they should be classed such or not

[5] Report of the Malaria Commission of the Royal Society.

The lymphocyte increase in typhoid fever —I have else here[8] drawn attention to the value of a marked increase the percentage of lymphocytes without any note orthy increase of the large mononuclear white cor- iscles in differentiating typhoid from malarial remittent vers, and subsequent experience of a large number of ises has amply confirmed, and in some respects extended, y earlier results My former paper on this subject as largely based on cases of fever in natives who ery frequently do not come to hospital until far on in ie disease, so that the great majority of the cases were not amined until the third or fourth week when a well

was nearly uniformly met with the present series in Europeans he earlier stages, so that they to the diagnostic value of this

iange in the blood In the following table the number of aminations in each week of the disease in which varying egrees of lymphocyte increase were found is shown in a onvenient form for studying the degree and frequency of the hange

TABLE IV —*Showing Lymphocyte Increase in Typhoid Fever*

First week—No increase = 26				Increased = 46				Total
umber of lympho cytes	0–20	20–25	25–30	30–35	35–40	40–50	50	
irst week	—	—	2	1	1	1	—	5
econd week	3	—	7	4	5	4	1	24
hird week	4	1	1	2	3	5	4	20
ater	4	3	1	3	2	7	3	23
Totals	11	4	11	10	11	17	8	72

f the 50 cases there were no increase in 12 and an increase i 38 cases or 72 per cent.

From the above table it appears that the lymphocytes ere increased above the normal limit of 30 per cent. in bout three quarters of the cases, and this change may even e found in the first week, in the majority of the cases in ie second week, and in almost three quarters of them during ie third week of the disease, when it frequently reaches a igh degree Its value, however, is even greater than these gures denote for as a rule the cases in which it is absent re of a severe type which can be recognised as probably yphoid fever at a glance, while in the mildest cases it is sually particularly well marked, that is just where it is most anted. The absence of the lymphocyte increase late in the

stablishment of immunity and the lymphocyte increase Vhen in a case of continued fever the lymphocytes are icreased, and especially if over 35 per cent are found and t the same time there is no marked increase of the large iononuclears (which is so characteristic of malaria) then it s exceedingly likely to be a case of typhoid fever In cases f malarial remittent fever a similar count may rarely be obtained at the height of the daily rise of temperature, but in these cases the total number of leucocytes present will be very greatly reduced, usually to about 1000 per cubic millimetre—a condition which I have only seen in malarial and never in typhoid fever cases It is important, then, to note the percentage of large mononuclears met with in the series of typhoid fever cases, so that they may be compared with that of the malarial series to be dealt with presently Table V shows the results obtained

TABLE V —*Showing Large Mononuclear White Corpuscles in Typhoid Fever*

—	Normal			In excess		Total
Percentages	0–4	4–8	8 10	11 15	+15	—
Total examinations	37	24	4	4	3	72
First and second weeks	—	—	1	1	1	—
Third week	—	—	—	—	—	—
Later	—	—	3	3	2	—

From this table we find that in only 11 out of 72 examinations were the large mononuclears above the normal 8 per cent and in only three was the increase found during the first three weeks of the fever when the diagnosis might possibly have been in doubt. In one of these malarial parasites were found in the blood, the large mononuclears having numbered 18 per cent., and in another, in which 15 6 per cent were found, typhoid fever had supervened on a malarial fever, and in the remaining one there were reasons for believing that the typhoid fever was also complicated by malaria. The highest number of large mononuclears met with in a patient suffering from typhoid fever was 18 per cent, and malarial parasites were also found in the blood at the same time as a Widal reaction was obtained in a dilution of 1 in 100 (Case 6) In the remaining instances in which over 10 per cent were found the fever had reached from the thirty-fourth to the seventy ninth day and normal numbers of large mononuclears had been found in the earlier stages It is clear, then, that the occasional high percentage of these corpuscles in the blood of typhoid fever patients in the earlier stages of the disease usually denotes coincident occurrence of malarial infection which requires appropriate treatment, while in the later stages there may be some increase after the end of the third week in prolonged cases of pure typhoid fever, but this can scarcely mislead at such a late period of the disease A similar late large mononuclear increase has been recorded by Winter in Dublin[9] As we shall see immediately, a marked large mononuclear increase is so characteristic of malarial remittent fevers that its absence should lead to a suspicion of typhoid fever as against malaria, and that, too, even in the absence of a marked increase of the lymphocytes I have several times correctly diagnosed cases of typhoid fever in an early stage by this point, leucocytosis of pneumonia or cerebro spinal fever, &c, being also absent

TYPHOID FEVER IN NATIVES OF INDIA.

The frequency or otherwise of typhoid fever in natives of India was a perennial source of controversy in the pre Widal days As the subject is of great importance in relationship to the so called "non malarial remittent" fever of Dr Crombie it must be briefly referred to here, reference being made to a paper in which I dealt more fully with the subject a year ago for further details[10] Dr Crombie used to hold that typhoid fever very rarely occurs in natives and supported his conclusion by the statement that only three cases were returned as such in the large Medical College Hospital in the ten years 1880 89 By means of the serum test I found twice that number in the wards of the same hospital at one time and 11 cases in five months That number has in the course of 18 months been increased to 26 together with others in different hospitals and institutions in Calcutta, while reactions in high dilutions have also been obtained with the blood of native fever patients sent to me from various parts of Bengal Lamb has also obtained similar results in Bombay Clinically they do not differ essentially from the same disease in Europeans, only they tend to be more severe and fatal on account of the late stage of the disease in which they are commonly admitted, while bronchial affections are more common and diarrhœa less so than in Europeans, the stools being less typical, probably on account of the largely vegetarian diet of the great majority of the patients. The disease is also somewhat more common among children in natives, no doubt on account of their greater exposure to insanitary conditions. More important are the duration and type of the fever for comparison with those of other fevers. Out of 21 cases of typhoid fever in natives, with confirmation by Widal's test in the Medical College Hospital, of which I have full notes, five died before the end of the third week. Of the remainder all but one suffered from fever for three weeks or more, the exception having only given a reaction in a dilution of 1 in 20, and clinically also the diagnosis of typhoid fever was not quite beyond suspicion. Nine cases lost their fever between the twenty-first and the twenty-fifth days and the other six at later dates. These results agree closely with those recorded above in typhoid fever in Europeans and lend no support to the view that the disease is commonly abortive and of short duration in natives, although it may very occasionally be so. With regard to the type of the disease, in just half of the cases the "continued" type, as defined above, was observed; that is a somewhat smaller proportion than in Europeans, possibly due to the greater frequency of complication with a malarial element in the case of natives. In the other cases the fever was of a remittent type, although usually less markedly so than in true malarial remittent fevers. Abdominal symptoms, such as distension, tympanites, or pain, were nearly always met with at some period of the disease—a most important clinical diagnostic feature. With regard to the serum test, reactions in dilutions of 1 in 20 only were obtained in two; in 1 in 40 in six more; and in 1 in 100 in 18 cases—a result closely comparable with those in Europeans. Similarly with the leucocyte count: in two-thirds of 30 examinations a lymphocyte increase to above 30 per cent. was found, in all but four of which over 35 per cent. were present. On the other hand, in 27 examinations the large mononuclears were not over the normal limit of 8 per cent., and in the remaining three cases they were under 9 per cent., which, we shall see presently, clearly differentiates them from malarial remittent fevers.

---

[8] Ibid April 5th, 1902

[9] Dublin Journal of Medical Science, October 1901

[10] Indian Medical Gazette, January 1902

The above brief summary is sufficient to prove that typhoid fever is a common continued fever of natives of India and that it differs in no noteworthy respect from the same disease in Europeans in this country.

MALARIAL REMITTENT FEVERS.

We next have to deal with the great class of malarial remittent fevers the differentiation of which from typhoid fever in their earlier stages is in many instances one of the most difficult problems in tropical medicine. In the first place we must define the term "remittent" and draw some line between it and intermittent cases, for these terms are often very loosely used, different meanings being attached to them by various observers. For instance, in many cases of malignant tertian malarial fever the temperature remains high for some 36 hours and then falls to about normal for a few hours before the same cycle is repeated. This is essentially an intermittent type and the term "remittent" should be reserved for those cases in which the temperature remains well above the normal line for some days. In an analysis of the General Hospital records to ascertain the seasonal prevalence of the different forms of fever, therefore, I adopted the plan of classing cases under the head of "remittent fever" only when the temperature did not fall below 100° F. for two or more clear days and the following data are also based on a series of cases complying with this definition. I find in my tables 29 cases of acute malarial remittent fever in the European General Hospital which both the clinical course and the result of the exhibition of quinine clearly proved to be malarial. Further, they were all examined by the serum test for both typhoid and Malta fever with negative results in all but one man who had suffered from a severe attack of typhoid fever in South Africa two years before and whose blood gave a reaction in a dilution of 1 in 40. All these cases had been liberally dosed with quinine before I had an opportunity of examining their blood, so that the fact that in only a small proportion of them were malarial parasites found in no way negatives their malarial nature. Moreover, as we shall see presently, nearly all of them showed the typical large mononuclear increase of malaria, which fortunately is not masked by quinine and hence has a peculiar diagnostic value in such a series as this. By analysing them in a similar manner to the former series of typhoid fever cases we shall be able to get a clear idea of the diagnostic value in the two fevers of the blood changes; and if these are found to afford sufficient ground for believing that the two diseases have been separated with a considerable degree of accuracy then a comparison of the course and symptoms in the two series may be expected to furnish us with some useful data for their clinical diagnosis. They may be conveniently considered in the same order as in the cases of typhoid fever.

The qualifying term "acute" malarial remittent fever is used above in order to exclude cases of chronic malarial fever —best designated by the valuable old, but comprehensive, term malarial cachexia (which workers in the malarious parts of India desire to see restored to the official nomenclature of the Royal College of Physicians of London)—for in these also the remittent type of fever occurs now and then interspersed in the generally intermittent course of the disease. As I have recently showed elsewhere,[11] there are certain special blood changes of great importance found in such cases—namely, an extreme reduction in the total number of the white corpuscles, accompanied by a great relative reduction in the polynuclears, with a corresponding increase in the percentage of the lymphocytes as well as the typical increase of the large mononuclears of acute malaria if marked fever is present. These changes are of great prognostic value and I have suggested that they may explain the great resistance of such cases to ordinary doses of quinine and also the success I have recently had with very large ones by the mouth or the hypodermic use of the drug in chronic malaria. Interesting as this class of cases are they fall beyond the scope of the present paper, for they cannot well be mistaken for typhoid or other "continued" fevers.

Age incidence.—This is shown in Table VI.:—

TABLE VI.—*Showing Age Incidence.*

Years ...	5-10 ...	11-15 ...	16-20 ...	21-25 ...	26-30 ...	31-40 ...	Over 40
Cases ...	2 ...	3 ...	10 ...	4 ...	6 ...	3 ...	1

This shows a very similar incidence to that of typhoid fever, so that no diagnostic import attaches to the ages of the patients in the case of these two fevers.

The duration of the fever.—This is of much greater importance, for we have seen that typhoid fever very rarely runs a course of much under three weeks. In Table VII. the total duration of the fever both before and after admission is given in the second line and the time the fever lasted under treatment in the hospital, where quinine was always given in smaller or larger doses, is shown in the third line:—

TABLE VII.—*Showing Duration of Fever.*

Duration of fever in days...	1-7	8-14	15-20	21-25	26-30	31-40	Over 40
Total duration ...	3	8	8	2	4	1	3
Fever in hospital...	12	11	3	2	1	—	—

Here we see a marked difference from typhoid fever the duration of which exceeded 20 days in four-fifths of the cases and in only 4 per cent. ended within two weeks. Still more marked is the difference in the duration of the fever after coming under treatment, for the majority of the cases of typhoid fever were admitted during the first week of the disease and therefore had two weeks or more fever in hospital, while in the case of the malarial remittent fevers under treatment with quinine almost four-fifths came to an end within 14 days of admission and over one-third within one week. This is in agreement with the conclusion I came to over a year ago[12] with regard to continued and remittent fevers in natives (excluding cases of malarial cachexia)—namely, that upwards of 80 per cent. of such fevers which lasted three weeks or more were typhoid fever.

Clinical characters.—The chief points in which acute malarial remittent fevers differ from typhoid fever are mainly of a negative character. Thus, in the former diarrhœa, abdominal distension and pain, rose spots, and bronchial catarrh are absent or rarely met with. Hæmorrhage from the bowel is very rare except when dysentery complicates the disease. On the other hand, the spleen is much more frequently and markedly enlarged in the malarial remittent fevers and the liver is also frequently to be felt below the ribs. A history of chill or rigors or fever on and off for some time previously is in favour of a diagnosis of malarial remittent fever but it is also not very rarely obtained in cases of typhoid fever in the tropics so that it cannot be relied on very much

---

[11] Ibid., November, 1902.
[12] Ibid., January, 1902.

The temperature curve —This is of great importance, for although the remittent type is commonly seen in typhoid fever yet the rises and falls are, as a rule, much more regular and punctual to the hour in malarial remittent fevers and also usually of greater amplitude When the rises occur regularly at some other period of the 24 hours than the afternoon or early evening, the case is nearly certain to be malarial Of even greater value is the fact that in all my charts I can only find one case of malarial remittent fever in which the temperature remained within 2° for upwards of 48 hours, and at a height of above 101°, unless there was some complication such as pneumonia Every other case in which this continued type of a high degree was present proved to be enteric fever and not malarial Of course a similar type is common in pneumonia but here the presence of leucocytosis will exclude uncomplicated typhoid fever As this continued type is most frequently seen during the first and second weeks of typhoid fever it is of very great diagnostic value and has frequently enabled me correctly to diagnose typhoid fever in an early stage of the disease before other definite symptoms were present, and I look on the establishment of this point by means of my study of a large number of four hour charts of continued and remittent fevers controlled by serum and blood tests as a most important practical outcome of this investigation The contrary, of course, does not hold good, for, as we have seen, the curve in true typhoid fever may be remittent or even rarely intermittent, and may also occasionally show as great regularity of the remissions as in malarial cases There remain, then, a number of cases in which the temperature curve will not be of any material service and it is in these that the serum tests and leucocyte counts are of such great value

The pulse rate —It is a well known feature of typhoid fever that the pulse may remain below 100 per minute persistently for days when the temperature is raised to 103° or 104°, especially in cases which are running a favourable course A large proportion of my cases have shown this point in a well marked degree On the other hand I can only find one chart out of a number in which the pulse rate was recorded in which it remained persistently below 100 per minute in malarial remittent fevers and this was a very mild one in which the temperature never rose above 101 2° This slow pulse rate when present is a valuable point in favour of
nittent fever, while it is most
ses which are most difficult to
ans

already mentioned, all the cases here dealt with had been saturated with quinine for some days before I was able to examine them, so that the parasites were seldom found in the single slide made on the one or, rarely, two occasions when the blood was tested When present they were always of the malignant tertian variety, but out of the 29 cases referred to above in only six of them, or 20 7 per cent, were they detected Romanowsky's stain being always used. This agrees closely with Captain Delany's results in the Medical College Hospital, Calcutta, in very similar circumstances[13] In two cases however, the temperature had finally reached normal before they were examined, and in three more it was on its final fall If these are excluded as extremely unlikely to show parasites, then they were found in 25 per cent of the remaining cases

The serum reaction, as already mentioned, was negative except in one man who had had typhoid fever two years before. That for Malta fever was also negative, except that in one or two cases a clumping in a dilution of only 1 in 10 occurred, as happens occasionally, in my experience in normal bloods and in those of persons suffering from various diseases other than Malta fever[14]

The large mononuclear increase in malarial remittent fever —Table VIII shows the percentage of large mononuclears found in 34 examinations of the blood arranged in the same way as that already given for typhoid fever cases except that they are classed in accordance with the temperature when the film was taken instead of the week of the disease—the former having an important influence, for, as shown by Dr Christophers and Dr Stephens[15] the large mononuclear increase becomes less marked as the temperature rises

TABLE VIII —*Showing the Large Mononuclear Increase in Malarial Remittent Fevers*

—	Normal or slightly increased			Markedly increased 30			Total
Percentages	0-4	4-8	8-11	11 15	15-20	Over 20	
Temp - 101° F	0	2	1	7	7	4	21
Temp + 101° F	0	1	0	8	3	1	13
Total	0	3	1	15	10	6	34

We see from Table VIII that in only four out of 34 examinations were the large mononuclears less than 11 per cent, and in one of these they were increased over that number at a second examination when the temperature had fallen to normal This is just the reverse of what we found to be the case in typhoid fever, in only two cases of which during the first three weeks of the disease were over 11 per cent large mononuclears found and these were complicated by malaria, so that by the leucocyte count alone the two forms of remittent fever can almost invariably be differentiated It will also be observed that the highest percentages of large mononuclears are met with in examinations made when the temperature is below 101°, as compared with those made when it is above that point which is in accordance with the observations of other workers on malaria, as mentioned above

TABLE IX —*Showing the Lymphocytes in Malarial Remittent Fevers*

—	Normal 23			Increased 11				Total
Percentages	0-02	20-25	25-30	30-35	35-40	40-50	60	
Number of examinations	7	8	8	4	3	3	1	34

From Table IX we see that more than two thirds of the
[illegible] e lymphocytes while a marked
instead of being the rule, as
points taken together are of
rential diagnosis of the two
fevers and will very rarely indeed mislead if the precaution is taken of examining the blood in the morning during a remission of the fever in cases suspected to be malarial, for it is at this time that the increase of the large mononuclears is best marked

The quinine test —Before leaving the subject of the malarial remittent fevers we must discuss how far the diagnosis of malarial remittent fever made by means of the differential leucocyte counts has been borne out by the results of subsequent anti malarial treatment, for unless they will stand this test in patients not yet the subject of marked malarial cachexia they cannot be relied on Now in several of these cases the patients had been taking quinine in 10 grain doses three times a day by the mouth for a week or more with little or no effect on the temperature curve and this would be held by some to be sufficient to prove that they were not of a malarial nature This opinion may be true of malaria in some countries but it is utterly untrue of many cases of malaria as seen in Lower Bengal and other parts of India—a point on which I cannot lay too much stress as this fallacy has been responsible for much lingering fever and many deaths During the last fever season at the Calcutta General Hospital as soon as a large mononuclear increase has been found in cases which have resisted quinine by the mouth the drug has been given hypodermically in from 5 grain to 10 grain doses twice a day, the bi hydrochlorate being used and injected into the subcutaneous tissues. The results have been admirable for in case after case the temperature has fallen to normal in two or three days The leucocyte count, then has come triumphantly out of the ordeal of the quinine test, although in most of these cases no parasites could be found in the peripheral circulation and fortunately no opportunity of finding them after death has occurred, although a few years back necropsies were not very rare in this class of cases especially when quinine was ordered to be given only when the temperature was below a certain point, with the result that the drug was reduced in direct proportion to the severity of the case, instead of being increased.

[14] Indian Medical Gazette October 1902.
[15] Report of the Malaria Commission of the Royal Society

Are there any continued or remittent fevers other than typhoid fever and malarial fever?—As already mentioned, this investigation was started with the object of separating out the known fevers with a view to studying the undifferentiated ones described clinically by Dr. Crombie and others, with whom I quite thought that such existed. So far I have dealt with 50 cases of typhoid fever and 29 cases of acute malarial remittent fever. In addition to these, six cases of chronic malarial remittent fever and 11 more cases of malarial intermittent fever are included in my European series, making a total of 96 cases out of the 126 cases examined in the General Hospital. Among the remaining cases we first have a miscellaneous assortment, including cases of phthisis, pneumonia, cerebro-spinal fever, liver abscess, cellulitis, and other local inflammatory conditions, all showing varying degrees of leucocytosis which in several cases materially assisted the diagnosis. For example, in one case malarial parasites were believed to have been found by the medical officer in charge but the fever increased steadily in spite of hypodermic injections of quinine and I was asked to examine the blood. Finding leucocytosis (13,000) and pain over the liver and in the right shoulder, I diagnosed liver abscess but the supposed parasite had greater weight than the leucocyte count and the patient was sent on a voyage to Colombo, where his liver abscess was successfully opened. In another case a child suffered from an obscure fever and two examinations of the blood failed to reveal any evidence of either malaria or typhoid fever, the case soon after developing into one of tabes mesenterica. In two other cases an irregular fever with some degree of leucocytosis accompanied dysentery, probably of the amœbic type.

When all the above well-known diseases are excluded, what have we left in the way of continued fevers? Practically nothing. Some three or four cases, all in the first 20 examined when my experience was very limited, remain, and looking at the notes and charts of these in the light of my present experience I cannot find one which repeated examination would not in all probability have proved to be either typhoid fever or malarial. One of these I thought at the time might correspond with the type which Dr. Patrick Manson describes under the term "double continued fever" but I have since seen very similar cases which proved to be malarial and yielded to full doses of quinine. In my last 100 cases I have met with very few doubtful ones and none which I have any good reason for thinking might be a new and undifferentiated fever, disappointing as it is to have to say so. What, then, are the cases described by Dr. Crombie continued fevers?

"SIMPLE CONTINUED FEVER."

bie holds that three-quarters of the cases which gly returned under the head of ague belong to the he terms "simple continued fever." He describes them ushered in with a rigor, followed by high fever, with che and gastric disturbance, and lasting from three eight days, but sometimes resembling a mild attack of typhoid fever and going on for two, three, or four weeks, in which case he calls it "Calcutta fever." They are most commonly attributed to "exposure to the sun." Now in the year Dr. Crombie's address before the Indian Medical Congress on fevers was published I undertook an investiga- of 100 consecutive fever cases in a native regiment in Chota Nagpur; and a microscopical examination and an analysis of the symptoms convinced they were all malarial. "Simple continued fever," has been very commonly diagnosed in the Calcutta Hospital by those who had the advantage of study- under Dr. Crombie himself and several cases quite lly as he describes them, which had been diagnosed this term, are included in my table of cases. Each of showed the large mononuclear increase of malaria; several showed a typical tertian character, and they were each cured with quinine. I have not yet had an opportunity of examining these cases immediately on admission before they had taken quinine, so I am not prepared to state positively that there are not non-malarial fevers of this type; but if so I am certain that they are not anything like as common as Dr. Crombie holds, but I hope to be able further to investigate this point before very long. In the meantime some light may perhaps be thrown on the subject by a comparison of the seasonal incidence of the cases returned as simple continued fever and as malarial intermittent fever respectively; for if they are quite different diseases, and especially if the former is commonly due to exposure to the sun, this should be quite different, for the malarial season in Calcutta is the rainy one when the sun is seldom seen. In the lowest part of the accompanying charts the cases returned under these two heads month by month during the last three years are shown, the cases of malarial intermittent fever being represented by the uninterrupted lines and those of the simple continued fever by the broken ones. I find it has been more or less the custom in this hospital to look on short fever cases with any enlargement of the spleen as undoubtedly malarial and of those without any enlargement as being very probably "simple continued fever," especially if there was no history of chill or rigor. Now one of the first things which strikes a medical man on going to India is the frequency with which typical ague is absent in purely malarial fevers, especially malignant tertians. Further, in first attacks, which will be most frequent at the beginning of the fever season, the spleen will not yet be enlarged. Cases of malarial intermittent fever without enlargement of the spleen will occur in greatest numbers at the beginning and be fewest at the end of the malarial fever season when they will more frequently show an enlarged spleen due to repeated attacks of the disease. If now we examine the chart of the cases diagnosed under these two headings for the years 1900 and 1901 we see that in both years the two coincide very closely, both in monthly incidence and in number, the only difference being that in the first year the curve of the so-called "simple continued fevers" both rose and fell a month earlier than the malarial cases, this being precisely what might have been expected if all the cases were really malarial in nature but those without enlargement of the spleen had more frequently been wrongly called "simple continued fever." During the year 1902 it will be observed that this supposed new fever has nearly completely disappeared, especially during the malarial fever season, while at the same time greater attention has been paid to the use of the microscope in the diagnosis of the fever cases. This agrees with my former conclusion that nearly if not quite all of these short fevers are malarial in nature and that "simple continued fever," if it exists at all, is an uncommon disease and should not be diagnosed until malaria has been excluded by an examination for malarial parasites, or, if quinine has already been taken, also for the large mononuclear increase. It is also worthy of note in connexion with the supposed relationship between "simple continued fever" and "exposure to the sun" that the cases returned under this head are fewest during the dry, hot months of March to May and greatest in the cloudy months of the rainy season. The existence of "simple continued fever" as a separate specific disease still remains to be proved.

"NON-MALARIAL REMITTENT FEVER."

Next we come to the fever which Dr. Crombie describes under the above term and which he regards as the most important tropical fever the specific organism of which awaits its discoverer. It has been a great disappointment to me not to have been able to find this fever to exist at all, as I believed it did when I began this investigation; but on reading over again Dr. Crombie's description of the disease the mistake into which he has fallen is quite easy to understand in the pre-Widal and leucocyte-count days. To make the matter clear it will be necessary to quote from his writings on the subject, bearing in mind his statement that true typhoid fever is very rare in natives of India and that only three cases were returned as such in the large Medical College Hospital in the ten years 1880–89. He summarises his description of it in these words: "This condition, one of persistent high temperature without any marked remission, a distinctly enlarged and congested liver with bilious diarrhœa, a congestion of the back of both lungs, and a low muttering delirium, is generally reached by the eighteenth to the twenty-fourth day. If coma supervenes the patient frequently dies at this period." He also states that quinine has no effect on the fever and that although he has seen it in Europeans yet "it is essentially a disease of natives and is not common after 30 years of age." With the exception of the absence of the yellow stools of typhoid fever in Europeans, no doubt owing to the vegetarian diet of most poor natives, this appears to me to be as good a description of typhoid fever as I have seen; yet it is prefaced by the remarkable statement that the fever "is by some considered to be a variety of typhoid fever *notwithstanding its divergence from all the symptoms of that disease.*" It agrees absolutely with the large number of cases of typhoid fever in natives verified by Widal's test during the last 18 months in the Medical College Hospital. Further, every such case with the continued type of fever and the absence of pneumonia, &c., in this hospital has proved on blood examination to be typhoid fever, so unless Dr. Crombie's fever has disappeared and typhoid fever has taken its place in the last few years there can be no doubt that his "non-malarial remittent fever" so commonly occurring in natives

mune to

find any case of such a continued fever as Dr. Crombie describes in the European General Hospital which has not proved to be either typhoid or malarial. It is worthy of note that he mentions that in his supposed new continued fever "the temperature is generally very high, touching 104° and 105° for a long part of its course, the daily fluctuations not exceeding 2° to 2·5° F." Now we have seen that all such cases have been proved by the serum test to be typhoid fever. This question may also be examined in the light of the seasonal incidence of typhoid fever as opposed to all other continued and remittent fever, including malarial remittent fever. The middle curve of the charts already referred to shows all the latter cases and the top one all the typhoid fever cases for the last three years in the European General Hospital. The maximum typhoid fever season is a very definite one, being reached in each year in the dry cold weather and hot weather months (for we have no spring in Bengal) in the first five months of the year and thus corresponds with the minimum malarial fever season. In the first two years charted there is also a slighter rise in the curve in the rainy malarious months but this is absent in the last year when the serum test was regularly used. It would, however, have appeared as usual had not several cases which had originally been diagnosed as typhoid fever proved by the blood examinations to be malarial remittent fever. The rainy season small rises of the first two years were probably also due to a few cases of malarial remittent fever having been wrongly diagnosed as typhoid fever. If now we turn to the curve showing all the other remittent fever cases (all truly continued ones having proved to be typhoid fever) we find that the main rise in the curve each year is in the same months as the malarial remittent fevers were most prevalent. This is in exact agreement with the conclusion I have arrived at by means of the blood tests—namely, that the only remittent fever other than typhoid fever is the malarial remittent fever. A few cases were returned as "simple continued fever" but they showed the remittent type, as defined in a previous section in this paper, and they also occurred most commonly during the malarial season. These curves of the seasonal incidence of the remittent fevers other than typhoid fever, then, strongly support the view that all such cases are malarial and give no indication of the existence of any new undifferentiated fever in the tropics, the existence of which I now very gravely doubt.

LOW FEVER.

Although this is not, strictly speaking, a continued or remittent fever, but rather an intermittent one, yet as it is included under the former term by Dr. Crombie it may be briefly referred to in conclusion. I am glad in this case to be able to agree with him as to the existence of this as a clinically distinct fever, on which the few observations I have yet been able to make may perhaps throw a little fresh light. Dr. Crombie well describes it as "a persistent low elevation of fever temperature unaccompanied by any constant symptoms, of indefinite duration, and uninfluenced either by quinine or arsenic. The temperature never falls below 99° F. and rarely rises above 101·5°." It is met with in Europeans and causes much depression and is generally cured by a change of climate or a sea trip. I have, however, several times known it to recur on the patient's return to Bengal, even after long leave to England. In my experience also the rise of temperature is always in the afternoon and never at other odd times, as not unfrequently happens in malaria. I have only had an opportunity of examining the blood in a few cases of this fever but have always found a marked reduction in the total number of leucocytes, accompanied by a disproportionate decrease of the polynuclears and a corresponding increased percentage of lymphocytes. Thus the total count may be from 2000 to 5000 per cubic millimetre, while the polynuclears will be reduced to about 50 per cent., or even less, and the lymphocytes increased to 40 per cent., or even more. Now this is just the change met with in cases of malarial cachexia in the absence of active malarial fever, when the large mononuclear increase is not found. On the other hand, we know that when the general health is bad there is a tendency for a reduction of the polynuclears to occur and it may well be that long-continued exposure to the debilitating influences of a tropical climate may produce an exaggerated condition of this nature. This weakness and want of resisting powers may lead to a loss of complete control by the heat-regulating centres, allowing the body temperature to rise with the afternoon increase of that of the surrounding atmosphere. Against this simple explanation is the fact that I have on two occasions known more than one member of a family affected by this form of fever, which might be held by some to indicate its being of a specific nature; but, on the other hand, in one of these instances one of the two sufferers subsequently developed an attack of ordinary malarial fever. The curative effect of a change of air also points to its being a condition of debility rather than a specific fever and, although I am not prepared to dogmatise on the subject with such a small experience, I am inclined to think that the disease is climatic rather than specific and that latent malaria may play a large part in its causation. With regard to treatment, I have seen the fever disappear and at the same time the percentage of the polynuclears increase while oil of eucalyptus was being given—a drug which was suggested to me as useful in increasing the leucocytes by Sir Thomas Lauder Brunton; but my cases are too few to allow me to say definitely that the drug has a curative effect on this form of fever without further evidence.

MALTA FEVER.

This concludes the discussion of the different forms of continued fever which have been described as occurring in the tropics, with the exception of Malta fever. I have tested the blood of upwards of 100 cases of continued and remittent fever by the serum test with the Malta fever micrococcus but with entirely negative results with the exception of an occasional reaction in a dilution of 1 in 10 only, which I have given reasons elsewhere [16] for believing to be of no diagnostic value. I find records of cases in the General Hospital in sailors who have recently visited Mediterranean ports, so that our medical officers are familiar with the disease both from this and from their Netley experience; but I find that they are nearly all agreed in considering that this disease does not occur indigenously in Lower Bengal, whatever it may do in North-West India. This statement is equally true of Assam in my experience which is confirmed by that of Major Ronald Ross.

ILLUSTRATIVE CASES.

The 12 following cases have been selected to illustrate the most important points dealt with in this paper. Cases 1 to 6 were cases of typhoid fever and Cases 7 to 12 were cases of malarial remittent fever.

CASE 1 (Serial No. 14).—Clinically this was a typical case of typhoid fever. The Widal reaction was negative on the fifteenth and twenty-fifth days. The lymphocytes increased to 38·2 on the fifteenth and to 47 per cent. on the twenty-fifth day, without any increase of the large mononuclears. A chart shows the continued type of fever from the ninth to the eleventh and from the thirteenth and fourteenth days, the temperature not having varied more than 2° on those days.

CASE 2 (Serial No. 19).—This was an abortive case of typhoid fever which was not suspected to be such until a brother and sister were admitted for fever and I found that all three gave a positive Widal reaction for typhoid fever, as did two more of the same family admitted shortly after. The fever in this case lasted only 14 days, yet the lymphocyte increase was very marked, 50·4 per cent. being found. In my experience these mild cases, as a rule, show it particularly well.

CASE 3 (Serial No. 48).—This case precisely resembled No. 2, except that the reaction for typhoid fever was negative on the seventh and twenty-first days; but the lymphocyte increase was well marked, 48·8 per cent., on the second examination, the large mononuclears not being increased, so that I am inclined to regard it as an abortive case of typhoid fever, or it may possibly belong to the class recently called paratyphoid fever. It was one of the very few doubtful cases in the series.

CASE 4 (Serial No. 41).—This case is of interest from several points of view. Clinically, it was for some time regarded as malarial in nature. On examining the blood on the ninth day the Widal reaction was negative but the lymphocytes numbered 39·6 per cent. without any increase of the large mononuclears and I diagnosed the case as typhoid fever on the strength of the leucocyte count. On the eighteenth day a second examination was made and now a positive Widal reaction for typhoid fever was obtained, while the leucocyte count remained practically the same, my diagnosis in the early stages thus being confirmed. I have met with other cases in which I have correctly diagnosed typhoid fever by the leucocyte count before the appearance of the serum reaction, the latter having given a positive result at a later stage of the disease. Another point of interest is the intermittent type of the fever, the patient having been a child, this type of typhoid fever not being very rare in children.

---

[16] Indian Medical Gazette, October, 1902.

CASE 5 (Serial No. 56).—This was a typical very severe case of typhoid fever which proved fatal on the nineteenth day. It shows well the "continued type" of fever and also illustrates the absence of the lymphocyte increase in very severe cases which has already been mentioned as being of prognostic value.

CASE 6 (Serial No 62).—This was a case of typhoid fever complicated by malaria admitted late in the disease and giving a serum reaction in a dilution of 1 in 100. The leucocyte count showed 18 per cent. of large mononuclears, which raised a suspicion of malaria and after some search a few malignant tertian malarial parasites were found. During convalescence a typical attack of malarial fever also occurred. The typhoid symptoms were severe and the temperature was of the "continued type," while the lymphocytes showed no increase during the height of the fever.

CASE 7 (Serial No. 7).—This was a case of remittent mlarial fever showing well-marked fall of temperature every other day and an increase of the large mononuclears to 16·4 per cent. and yielding to quinine in five-grain doses every four hours. The case was diagnosed at first as one of "simple continued fever" and I have seen other similar cases which proved on examination with the microscope to be malarial in nature.

CASE 8 (Serial No. 89).—This was a case of severe malarial remittent fever yielding rapidly to quinine hypodermically. This is the only malarial case I have yet met with in which the temperature remained within 2° F. for two days. At the first examination of the blood, when the temperature was high, 12 4 per cent. of large mononuclears were found but three days later, when it had fallen to normal, they numbered 28 per cent.

CASE 9 (Serial No. 92).—This was a typical case of a malarial remittent fever rapidly cured by the hypodermic use of quinine after the failure of the drug in 10 grain doses three times a day by the mouth. No parasites could be found when the blood was examined four days after admission, when much quinine had been taken, but 15·6 per cent. of large mononuclears were present which enabled a correct diagnosis to be made.

CASE 10 (Serial No. 107).—This was another case of malarial remittent fever diagnosed by the large mononuclear increase, in spite of a positive reaction for typhoid fever due to a severe attack of the disease in South Africa two years before, and successfully treated by hypodermic injections of quinine.

CASE 11 (Serial No. 115).—This was another case of malarial remittent fever with 21·2 per cent. of large mononuclears and scanty malignant tertian parasites where recovery rapidly ensued with quinine injected hypodermically after failure of the drug by the mouth.

CASE 12 (Serial No. 122).—This was a case of malarial fever showing a double daily rise of temperature and was very resistant to treatment with quinine. The large mononuclears numbered 16·4 per cent. The patient left the hospital unrelieved. No parasites were found on the single occasion when the blood was examined after much quinine had been taken. These cases of double daily rise are in my experience particularly difficult to treat and they deserve closer examination.

CONCLUSION.

The general conclusion arrived at by the careful clinical and pathological study by modern blood tests of a large and consecutive series of cases of continued and remittent fevers in both Europeans and natives in the hospitals of Calcutta, then, is that only two forms exist, at any rate of long duration—namely, typhoid fever and malarial remittent fever. Further, these can be distinguished in a considerable proportion of the cases by purely clinical methods, of which the temperature curve and pulse-rate and presence or absence of abdominal symptoms and the action of quinine are the most important. The remainder can be differentiated by the serum test or by the differential leucocyte count in all but a very few exceptional cases, the leucocyte count being of special value in the tropics on account of its being available when parasites are absent as a result of previous quinine treatment and its not requiring a laboratory—laboratories being very few and far between in the tropics at the present time—while it also has some prognostic value.

"Simple continued fever," if it exists at all as a separate entity, which still remains to be proved, is very rare indeed as compared with malarial fevers. The so-called "non-malarial remittent" fever in natives has been shown by the serum test to be nothing but typhoid fever. Low fever is distinct clinically, but is probably the result of the debilitating influences of prolonged residence in a tropical climate, including latent malaria, and is not a new specific fever. Malta fever does not occur, or at least is exceedingly rare, in Lower Bengal and Assam.

ON CASES OF UNCOMPLICATED MYOCARDITIS IN CHILDREN.[1]

By GEORGE CARPENTER, M.D. LOND.,
ASSISTANT PHYSICIAN TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN; LATE PHYSICIAN TO THE EVELINA HOSPITAL FOR SICK CHILDREN.

MYOCARDITIS has been divided into parenchymatous and interstitial and the lesions encountered are either circumscribed in single or multiple areas or are diffuse in their distribution. Further, the parenchymatous and the interstitial changes in the cardiac walls, although they may occur independently, are not infrequently associated in varying degrees. The degenerative changes in the muscle fibres, in the shape of albuminous, fatty, and waxy alterations caused by toxin poisoning, are met with in the initial stages of the infectious diseases and occur during convalescence; these also arise from other disorders and are now well known in the post-mortem room, but rarely is it possible to diagnose these changes during life, though they may be suspected. But parenchymatous myocarditis is not necessarily a fatal complaint, even when the symptoms are extremely well marked, as an illustration of my own, to be related later, will show.

Interstitial myocarditis, which is looked upon as a rare disease, is met with as an acute disorder, or as a chronic complaint of the cardiac wall which is thought to be rarer still. Of 56 cases of chronic myocarditis collected by Quain, but three occurred in children.[2] The commonly recognised causation of the acute disorder is pyæmia from bone and joint troubles. The common sequence is the formation of an abscess in the heart wall which either bursts into the pericardium, producing pericarditis, or into the endocardium and originates an acute cardiac aneurysm. Of 25 cases of abscess of the heart collected by Quain 14 of them occurred under 15 years of age.[3] On the other hand, pyæmic pericarditis may be associated with, and not be the cause of, interstitial myocarditis.

Acute myocarditis of rheumatic origin must be here mentioned, for although perhaps the changes in the heart muscle are usually more of the nature of parenchymatous degeneration than of interstitial inflammation, nevertheless these conditions are usually associated. Acute myocarditis has been found in connexion with old and with recent valvular disease and also with pericarditis. It has also been met with in scarlatinal pericarditis.

In regard to chronic interstitial myocarditis Dr Theodore Fisher[4] has called attention to the fact that small fibroid patches are frequently seen scattered through the heart muscle in fatal cases of mitral stenosis. He gives an illustration of fibrous myocarditis in a lad 18 years old, associated with old aortic disease. He also relates a case of an infant four and a half months old who was found post mortem to have fibroid disease of the cardiac muscle and stenosis of the aortic valve Chronic interstitial myocarditis may also be associated with adherent pericardium but it is not, however, in every case of hypertrophied heart from adherent pericardium that such changes can be found microscopically. Sclerotic patches in the heart may also take their origin in occlusion of the coronary arteries, syphilitic or otherwise. Syphilitic myocarditis, in the shape of solitary and multiple gummata, has been recorded in infants and children and Hektoen[5] has published a case of syphilitic interstitial myocarditis in an infant six weeks old. Dr. J. Porter Parkinson[6] has also shown to the society a syphilitic nodule in the heart of an infant, aged three months, which was composed of young inflammatory tissue in various stages of development, the adjacent muscle being infiltrated and destroyed.

Judging from the paucity of the literature on this subject it is a malady about which little is known and which therefore requires further attention on the part of those specially studying children's complaints. The following striking examples of so rare an affection as uncomplicated myocarditis appear to me to be of sufficient interest to bring them to the notice of members of this society, in the hope that by calling attention to myocarditis and to the necessity for combined action our knowledge on this subject may be materially strengthened thereby.

CASE 1.—The patient, a girl, aged six years, was the child of healthy parents, but with a strong family history of phthisis. She had a rash on her buttocks and "snuffles" soon after birth. She had been ailing for a month, her illness commencing with enlarged glands in the neck, and her mother said that she had wasted and suffered from a swollen abdomen and complained of pain at the pit of the stomach. When she was admitted into the Evelina Hospital on Sept. 3rd her face was dusky and her lips were blue. The cardiac impulse, which was feeble, was felt with difficulty outside the nipple line in the fifth interspace. The dulness commenced at the third left costal cartilage and extended well to the right of the sternum. A whistling systolic bruit was heard over the cardiac impulse and a systolic thrill was felt on placing the hand over the cardiac area. There were no adventitious sounds to be heard in the lungs. The abdominal walls were flaccid and the liver, which was pulsating, reached almost to her umbilicus. The spleen was not enlarged. She passed 18 ounces of urine during the first 24 hours; it was of a specific gravity of 1026 and it contained about one-third of albumin. The pulse-rate was 132 to the minute, the respiration-rate was 56 to the minute, and the temperature was 97·6° F. By the 6th the bruit was not to be heard and the liver was returning to the costal margin. Her general condition had greatly improved. On the 12th she was still blue round the mouth. The cardiac impulse, which was exaggerated, was felt half an inch outside the nipple line. There was no epigastric impulse and the area of cardiac dulness was not enlarged to the right. The first sounds at the apex and the left base were reduplicated. The liver was now on a level with the costal margin. The specific gravity of the urine was 1024, 18 ounces were passed, and it contained one-eighth albumin; there were no casts. The temperature was still subnormal. The pulse-rate was 100 to the minute and the respiration-rate was 32 to the minute. On the 15th there was a trace of albumin in the urine, on the 16th one-fortieth, on the 17th there was none, and it was subsequently free during her stay in the hospital. On Oct. 1st she was found to have paralysis of the soft palate and the knee-jerks could not be obtained. By the 22nd food ceased to pass by the nose and the soft palate had in great meas [illegible] nt. On Nov. [illegible] lth with a so [illegible] history revealed the fact that three weeks before her admission into the hospital she had "patches" on the throat for which the medical attendant ordered a paint, but she was not ill enough to be confined to her bed.

CASE 2.—The next case is that of a girl, aged nine years, who was admitted into the Evelina Hospital on Sept. 2nd for a swollen abdomen and shortness of breath. The former trouble was supposed to have started in the preceding January. Her father suffered from heart disease. On admission she was a well-nourished, rosy-cheeked child and the most striking features of her case were a regurgitant venous pulse in the neck and an obviously pulsating liver. The pulse-rate was 112 to the minute, the respiration-rate was 46 to the minute, and her temperature was normal. The cardiac impulse was half an inch outside the nipple line; it was not well defined. There was a suspicion of a thrill to be felt there. The area of dulness, which commenced at the left third costal cartilage, extended half an inch to the right of the right sternal margin. There was no bruit. The lungs were normal. The spleen was not enlarged. The free edge of the liver was a hand's breadth below the costal margin in the nipple line. The urine was free from albumin. Whilst under observation she had paroxysmal attacks of facial cyanosis. Sometimes her lips were blue and sometimes the face was flushed. By Sept. 9th the liver had decreased in size and pulsation was not so marked. Several examinations of the urine had been made prior to this date but with negative result. On the 11th suddenly the face became very blue, the eyes were fixed and the limbs were rigid, the pulse was imperceptible at the wrist, and she died.

At the post-mortem examination the lungs were found to be very dropsical. The pericardium was healthy. The heart weighed nine ounces.[7] The left ventricle was pale, hypertrophied, and showed tabby-cat striation. The left auricle was dilated, thin, and pale. The endocardium was smooth. The mitral valve showed hæmorrhages at its root and in the valve itself; it admitted three fingers. The aorta presented patches of atheroma above the left coronary artery. The right ventricle was considerably dilated, pale, and showed tabby-cat striation. The right auricle was also much dilated, and its substance was pale. The liver, which was of the "nutmeg" type, weighed 2 pounds 14 ounces. The kidneys weighed 7½ ounces; they were heavy, hard, and leathery. The glomeruli were injected and the vessels of the medulla stood out prominently. The spleen was not enlarged. The stomach was congested.

Under the microscope the muscular fibres of the heart, for the most part, showed well-marked longitudinal striæ. In places the transverse striæ were well or fairly well marked but in others they required very careful focussing for their detection. On the other hand, though quite exceptionally, some fibres or portions of a fibre had a ground-glass appearance with obliteration of all striation. Accentuation of longitudinal striation and faintness or absence even of transverse striation were the prevailing characteristics. The muscle corpuscles with but few exceptions stained readily everywhere and many of them were very large and prominent. Certain microscopical fields showed an abundance of vessels; occasionally a small vein was found between the muscular bundles surrounded by a crowd of white corpuscles. Slight or an easily recognised increase of nucleation of the intermuscular areolar tissue with readily detected diapedesis of white corpuscles from the neighbouring capillaries was noticed throughout, together with proliferated areolar tissue cells; but here, again, areas were found where this had not occurred and the nuclei were quite within normal limits. Specimens stained with osmic acid were unaffected. The pericardium and the endocardium were free from abnormality.

In this case the cause of the interstitial myocarditis was not determined; in the next illustration, however, there appears to be no doubt that rheumatism originated the malady.

CASE 3.—A girl, aged eight years, was admitted into the Evelina Hospital on August 20th. Until two months previously she was perfectly well but she then developed rheumatism and subsequently suffered from chorea. On admission she had rheumatic synovitis of the left hand and wrist, the left ankle and the back of the corresponding foot, and a slight effusion into the left knee-joint. Her pulse-rate was 120 to the minute, the respiration-rate was 44 to the minute, and the temperature was 100·4° F. She had a loud mitral murmur which was audible at the angle of the scapula and a few rhonchi were detected in the lungs. Under salicylate of sodium the temperature had fallen to normal by the 27th. On Sept. 8th she was quite free from articular pains and fever, but there were great distress of breathing and considerable præcordial pain. Neither the pulse-rate nor the respiration-rate had increased in frequency. The cardiac impulse was much diffused; it was felt in the sixth interspace half an inch outside the nipple line. Systolic and presystolic murmurs were now heard and a systolic thrill was felt in the fourth left intercostal space. The liver was greatly enlarged and its lower edge reached as far as the umbilicus. The spleen was not increased in size. The urine was free from albumin. The ankles were œdematous. By the 11th the pulse had assumed a peculiar form; alternate periods of from 10 to 20 beats succeeded one another with great regularity. The rate of one set of beats was about 120 to the minute and the rate of the other set was 60 to the minute. The respiratory movements did not undergo any corresponding change. She died quite suddenly on the morning of the 12th.

[5] Carpenter, Syphilis of Children, p. 57.

[6] Reports of the Society for the Study of Disease in Children, vol. i., pp. 141, 142.

[7] Normal weight about four and one third ounces.

At the necropsy both lungs were extremely œdematous; many old, dry, cheesy deposits were found in the bronchial glands. The pericardium was normal. The heart was much enlarged. The left ventricle and auricle were dilated and the substance of the former was pale but not friable. The mitral valve, which was free from endocarditis, admitted four fingers. The aortic valves were healthy. Here and there in the substance of the ventricular wall yellowish dots and striæ were seen and the tips of the papillary muscles, especially those in relation with the mitral valve, were much spotted with yellowish deposits of about the size of a pin's head. An identical condition to the above obtained on the right side of the heart and here also the endocardium was free from disease. Under the microscope portions of the ventricular walls, taken at random, appeared to be quite healthy. On examining a dotted fragment it was seen that the muscular fibres in certain small areas had entirely disappeared, their place being occupied by countless oil globules of various sizes. Where it existed the change was extreme in degree though markedly circumscribed. The liver was greatly enlarged, it had a thick rounded edge, and was "nutmeg-like" on section. The spleen was normal. The pyramids of the kidneys were intensely congested. The other organs did not present any abnormality.

My next illustration is one of extensive focal myocarditis of a cicatricial nature and in this case the cause was not quite obvious, though possibly rheumatism played an important part in its genesis. There was no history or evidence of syphilis but there was a family history of consumption.

CASE 4.—A boy, aged 12 months, was admitted into the Evelina Hospital on Feb. 12th for disease of the hip-joint of four months' duration. Four months previously to Feb. 12th, according to the mother's statement, the back of the left foot, the left hand, and the wrist were swollen for about three days. During life the heart and lungs were apparently quite healthy. His temperature was above the normal whilst he was under observation, the highest point being 101° F. 48 hours after admission into the hospital he died suddenly.

At the necropsy miliary tubercles were found in the lungs, the liver, and the spleen. The synovial membrane of the hip-joint was thickened, but the bones appeared to be healthy. The pericardium was healthy. The left ventricle of the heart was dilated and scattered through its wall were a number of white areas, some rounded, others long and narrow, and many of them seemed to pass from the pericardium to the endocardium. The muscular substance where not involved looked healthy. There were two or three small rounded spots of infiltration in the substance of the right ventricle. The valves were normal. There was a valvular orifice at the foramen ovale.

On microscopical examination it was seen that areas of new growth invaded and broke up the muscle bundles from the pericardium to the endocardium. They were of varying sizes and when the microscopic sections were held up to the light it was seen that the outer half of the heart wall had been involved to the greater extent. Under the microscope were seen:—1. Wavy bundles of fibro-nuclear tissue with elongated wavy nuclei which sometimes invaded the muscle bundles and separated straggling muscle fibres from their fellows and here and there showed dense nuclear aggregation. Some of the muscle fibres thus isolated showed transverse striation, but in a few this appearance was lost and they were attenuated and opaque. 2. Areas where the connective-tissue fibrillæ were not so marked, though the nuclei were numerous and stained very well indeed. 3. Areas of varying sizes with increase of irregularly shaped nuclei in the intermuscular fibrillæ. The muscle corpuscles in such, in some instances, appeared to be quite large. 4. Areas, though few and far between, of perfectly healthy muscle fibre and connective tissue. 5. The endocardium much increased in thickness; the pericardium, where not joining the sclerosed tissue, unaltered. Although the endocardium was thickened the passage to it of sclerotic offshoots from the neighbouring muscle fibres was not a feature, but a nuclear increase in these was not uncommon, together with an undue separation of them from one another. The thickening often appeared to be quite independent of, and out of proportion to, any underlying mischief.

In conclusion, I should like to say that I have purposely confined myself to the narration of cases about which there can be no question as to the correctness of the diagnosis and I have intentionally omitted all reference to clinical cases of myocarditis complicated with pericarditis, peri- and endocarditis, adherent pericardium, and cardiac abscesses secondary to pyæmia.

I would also draw attention to the presence of systolic and presystolic murmurs in these free-from-endocarditis cases. It would appear that the mitral murmur merely requires for its production a leaking valve, that no roughness or irregularity of the segments is necessary to that end, and that a mitral murmur is not diagnostic of mitral endocarditis, though it is of mitral insufficiency; that the presystolic murmur and also the diastolic mitral murmur are indicative of a disturbance of the normal relationship that exists between the size of the mitral orifice and the left auricle; that when the latter is distended and the mitral ring is distorted the normal relationship disappears and leaves in its stead a *comparative* narrowing of the mitral orifice—in other words a comparative mitral stenosis for that particular heart; and that murmurs which depend upon these anatomical changes are indistinguishable clinically from the systolic and presystolic and diastolic murmurs of ordinary mitral disease and true mitral stenosis and that when these murmurs are present they are certainly much more in favour of endocarditis than the reverse by reason of the greater comparative frequency of that condition in heart disease, with the reservation that mitral stenosis in childhood is a rarity. Further, I would mention that I have heard similar murmurs produced in adherent pericardium associated with a dilated heart free from endocarditis as was pointed out by Dr. Theodore Fisher,[8] and in cases of pericarditis and myocarditis in which the endocardium of the valves was healthy.

But are not the clinical and pathological examples which I have just recorded the key to the explanation of the vanishing mitral murmurs which undoubtedly arise in some cases of acute rheumatism and of chorea and of the, in consequence, presumed recoveries from endocarditis and from supposed functional cardiac disorders? Do they not suggest that, in some instances at least, the supposed to be present endocarditis did not exist in reality? Do they not invite the conclusion that that which was present was a temporary softening and want of tone of the myocardium followed by dilatation and subsequent recovery, hence the appearance and disappearance of the mitral murmur. Such a condition of the cardiac muscle would also satisfactorily explain undue rapidity and irregularity of the heart's action in some cases of chorea. It would also explain in these cases of chorea one type of mitral murmur, that which is inconstant in both force and rhythm and is a not infrequent phenomenon in that disorder and which entirely disappears by the time the child has recovered or is found to have done so at a later visit. There is one strong point in favour of such a theory in explanation of these conditions and that is rheumatic myocarditis undoubtedly exists; we have clinical, supported by pathological, evidence of this. We also know that myocarditis can arise apart from endocarditis.

But myocarditis is not always attended by a mitral murmur even in an advanced condition of dilatation, nor is it always possible to map out the slightly dilated heart with precision; indeed, the softening might be so slight as to render its physical detection impossible but nevertheless capable of giving rise to definite symptoms. Some such supposition is also reasonable in explanation of the following examples of cardiac disturbance which I have noticed in rheumatic fever and with their recital I will bring this paper to a conclusion.

In one child, aged nine years, there was extreme weakness of the pulse without obvious lesion of the heart, though the first sound at the apex was almost inaudible. These symptoms lasted for about a fortnight and finally disappeared. In another child, aged five years, the pulse was intermittent and a little later a questionable systolic bruit was detected at the apex, but no further extension occurred, the intermission of the pulse disappeared, and the valvular sound once more became normal.

Welbeck-street, W.

MALIGNANT DISEASE OF THE COLON; 14 COLECTOMIES WITH 10 RECOVERIES.[1]

BY H. LITTLEWOOD, F.R.C.S. ENG.,
SURGEON TO THE LEEDS GENERAL INFIRMARY AND LECTURER
ON PRACTICAL AND OPERATIVE SURGERY IN THE
YORKSHIRE COLLEGE.

THIS paper is based on the study of about 26 cases of malignant disease of the colon which have occurred in my practice during the past four years. I have also included one case of malignant disease of the rectum; the disease was in the upper part and was removed by an abdominal proctectomy with end-to-end union, and for this reason I have added it to my list of colectomies. All the cases referred to were columnar carcinoma. I propose to deal with the subject under two headings (1) the diagnosis, and (2) the treatment. Under the heading of treatment I shall refer more particularly to the operation of colectomy. The cases of colectomy—14 in number—I have arranged in a special table, so that they can be more easily referred to; in these cases 10 of the patients made good recoveries and four died. In cases where colectomy is not possible or advisable owing to the general condition of the patient, the size and fixity of the growth, or the presence of secondary deposits, other operations may be required to relieve the patient, such as typhlotomy, colotomy, or the short-circuiting operation by lateral anastomosis.

DIAGNOSIS.

The diagnosis of malignant disease of the colon is sometimes quite an easy matter, but in the early stages of the disease it is often a matter of the greatest difficulty. Probably in all cases, when carefully inquired into, there is a history of increasing difficulty in getting the bowels opened. The patient may have noticed some blood or mucus in the motions. It is often only when these symptoms have increased so as to be a real inconvenience that the patient will consult a medical man. Many patients look upon constipation as an unimportant condition, for which they treat themselves by one or other of the natural mineral waters or patent pills which are now so seductively advertised. I feel that every patient suffering from constipation who consults a medical man should have the cause carefully in-[illegible] encouraging results by means of operation. If a patient has been in the habit of having his bowels opened at regular intervals and this regularity has been interfered with, so that the intervals have increased in duration or there have been one or more definite attacks of obstruction associated with "colicky" pains and the presence of blood and mucus in the motions, then a very careful examination of the anus and rectum must be made to ascertain if the cause of the obstruction is in this region. I have not had much experience in using specula for rectal examinations; I feel I can rely more on my sense of touch than on my sense of sight. If nothing is found by rectal examination—and it is a great thing to be able to exclude the presence of anything in the rectum—then the abdomen must be carefully examined.

On thinking over the cases of malignant disease of the colon which I have seen I divide them into two classes: (1) those in which a very definite tumour is present; and (2) those in which there is a constricting ring of growth which it is often impossible to discover by abdominal palpation. I am inclined to think that the larger tumours are invariably found in the cæcum, the hepatic flexure, or in the transverse colon and that beyond this point in the colon a large growth is the exception. The commonest seats in which to find carcinoma of the colon are the flexures; growths are most difficult to discover in the splenic flexure as it is so deeply hidden beneath the ribs; next to this those in the hepatic flexure are most difficult to find unless the tumour is of considerable size. A very large tumour *may be present and yet the patient may be unaware of* its existence until its presence has been pointed out by the medical man. In Case 12, where there was the largest mass which I have yet removed, the patient knew nothing of its existence. I think that it may also be stated, as a general rule, that the bigger the growth and the nearer it is to the cæcum the less likely is there to be obstruction—for this reason, that the motions are more fluid in the cæcal region and the larger growths are *less liable to contract and so to produce* a narrowing at the point of growth. If no growth can be discovered and still malignant disease is suspected, enemata and the inflation of the colon may sometimes give valuable help in diagnosis, or it may be necessary to give an anæsthetic and to make a more complete examination by palpation, specula, &c., and there are some cases in which we so strongly suspect carcinoma that we may feel it wise to recommend an exploratory operation. This we did in Case 4, and it is the earliest case of malignant disease of the colon upon which I have operated. A method which I learned from Mr. T. P. Teale I have sometimes found very useful when the patient is under an anæsthetic—i.e., to pass a pair of vulsella high up and to pull down the mucous membrane; by this means a growth high up in the rectum or sigmoid flexure may be brought within reach. Let me here point out the dangers sometimes associated with the use of enemata—I have twice seen fatal peritonitis due to a malignant ulcer bursting into the peritoneum during the administration of an enema, and in Case 6 I believe another enema might have produced a fatal result.

Up to the present I have assumed that we have been examining a case before any very definite obstruction has occurred. We will now consider those cases in which on the first time we see the patient acute obstruction is present and it may be that this is well marked before the patient has even [illegible] acute obstruc-[illegible] with or without [illegible] cold or discoloured extremities of fæcal toxæmia—and we may only be able to make a shrewd guess that the cause of the obstruction is malignant disease by excluding every cause which is more or less obvious. The age of the patient may help, but we must not forget that malignant disease may occur in quite young people; the youngest case (Case 11) in this series was 28 years of age.

TREATMENT.

If one sees the cases early and there is no intestinal obstruction then a primary enterectomy should be done and it often requires considerable judgment at the time of the operation to decide this point. I am quite convinced it was an error of judgment to perform a primary enterectomy in Case 11, but I shall refer to this later. There are several ways of doing the operation, many of them having good points, and naturally the surgeon will perform the operation best that he is most accustomed to. I am amongst those who believe that the suturing can be quite easily and efficiently accomplished without the aid of any of the special appliances which have been and are still being invented. Surgery is a handicraft and I hope will always continue so to remain, and not a branch of mechanical engineering, and it is the business of the surgeon to train his fingers so that he can use his needle with as much facility as a woman who makes any pretence to be a good needlewoman.

It is only during the last *four years that I have had many* opportunities of doing colectomy; my cases before this either had secondary growths or I thought that they were too [illegible] My first colectomy [illegible] was a woman with [illegible] typhlotomy and subsequently removed a mass from the ascending colon and united the divided ends by Halstead's method. Death occurred six months later when there were secondary deposits in the liver. Between this case and those which are included in the table of colectomies appended to this

[2] THE LANCET, Oct. 13th, 1894, p. 852.

TABLE SHOWING THE RESULTS OF 14 COLECTOMIES PERFORMED FOR MALIGNANT DISEASE OF THE COLON.

No. of case.	Sex.	Age.	Nature and position of disease.	History.	Signs and symptoms at the time of operation.	Nature and date of operation.	Result.	Remarks.
1	F.	57	Large mass in the cæcum.	The patient had been ill for two months. She had had a great deal of pain in the right iliac region and the back. There was some constipation but no vomiting. She had lost weight.	There was a large tumour in the region of the cæcum, which could be both seen and felt. The patient's chief symptom was pain.	On June 18th, 1900, the cæcum and part of the ascending colon and mesentery were removed; the ileum was stitched to the cut end of the ascending colon.	A good recovery.	In this case there was no obstruction. The presence of the tumour and pain were the prominent features. No secondary growths were noted at the time of operation.
2	F.	46	Large mass in the hepatic flexure.	The patient had been ill for about five months and was getting thinner. She was suffering from constipation and occasional attacks of vomiting were noticed.	There was a large tumour in the hepatic flexure. Constipation was present.	On July 25th, 1901, about ten inches of the colon and the corresponding mesentery were removed. End-to-end union was effected.	A good recovery and the patient is apparently now quite well.	The case was seen with Dr. A. Dennison of Burley. The tumour was the prominent feature in the case. No secondary growths were noticed at the time of operation.
3	M.	34	Large mass in the transverse colon.	The patient had complained of a dragging pain in the lower part of the abdomen since August, 1900. The tumour was noticed a month later. There was no constipation.	There was a tumour in the lower and right part of the umbilical region. It was freely moveable and was of about the size of a closed fist.	On April 22nd, 1901, about six inches of the transverse colon, including growth, with mesentery, were removed. End-to-end union was effected.	A good recovery and the patient is apparently now quite well.	The case was sent to me by Mr. Edwin Lee of Dewsbury. The tumour was the prominent feature of the case. No secondary growths were noted at the time of operation.
4	M.	54	A small growth of the size of a florin in the splenic flexure near the mesenteric border involving about half of the lumen.	The patient thought that in September, 1900, he had strained himself whilst lifting; since then he had had on two occasions constipation and obstruction lasting for a fortnight. When in bed he was free from pain. He had been getting thinner.	The patient was suffering from constipation. There was no obstruction at the time of operation or evidence as to the cause of the obstruction. Early malignant disease was suspected.	On Nov. 22nd, 1900, a small malignant mass which was found in the splenic flexure was removed. End-to-end union was effected.	A good recovery and the patient is apparently now quite well.	The growth appeared to produce obstruction by tilting or possibly by producing a slight intussusception.
5	F.	37	Constricting mass of malignant disease in the splenic flexure.	The patient was apparently quite well until August 25th, 1900, when symptoms of complete obstruction revealed themselves.	There were well-marked signs of complete obstruction. The abdomen was distended, with well-marked visible peristalsis.	On Sept. 5th, 1900, the abdomen was explored in the middle line. The cæcum was enormously dilated and somewhat rotated. Typhlotomy was performed. On Oct. 22nd, 1900, a small ring of malignant growth was found in the splenic flexure and removed. End-to-end union was effected.	A good recovery and the patient is quite well at the present time. There is a little discharge at times from the typhlotomy opening.	At the first operation the cause of obstruction was not found. It was a very small ring of growth in the splenic flexure an the intestines we enormously di tended. The descen ing colon was al distended, probabl the result enemata.
6	M.	52	There was a mass of malignant disease surrounding the lower part of the sigmoid flexure at the pelvic brim. In one part the growth had ulcerated and in this cavity an orange-pip had lodged.	The patient had complained of pain in the body and of constipation for 12 months. Eight months before he had a violent attack of pain and vomiting and since then he had taken medicine regularly. He had lost weight.	During his stay in the infirmary before the operation the patient was examined several times, but the cause of the obstruction could not be discovered. Malignant disease of the colon was suspected. The bowels could be opened by means of purgatives and enemata.	On Dec. 17th, 1900, the abdomen was explored in the middle line and the mass of growth found in the lower part of the sigmoid flexure. About four inches of bowel were removed. The gut was severed through the lower part of the sigmoid flexure and the upper part of the rectum. End-to end union was effected.	A good recovery.	The stitching was ver difficult. On ex mining the specime it looked as if anothe injection would hav burst through th base of the ulcer an so might have pr duced a fatal per tonitis.
7	F.	43	Malignant growth surrounding the rectum; the lower limit could just be felt. It appeared moveable by bimanual examination.	Six months before operation the patient began to suffer from constipation. This at times alternated with diarrhœa and the passage of blood and slime. She lost weight	There was a tumour at the upper part of the rectum with passage of slime and blood.	On Feb. 27th, 1902, the patient being in the Trendelenburg position, the abdomen was opened in the middle line and about four inches of rectum were removed End-to-end union was effected.	A good recovery and the patient is quite well at present.	This was a ver difficult operation There was no evi dence of secondar growth. The case wa sent to me by D D. J. Macaulay o Halifax.
8	F.	53	Constricting ring of malignant disease in the hepatic flexure.	The patient had suffered for several months from chronic constipation which culminated in an attack of acute obstruction which was complete for a week.	There were complete obstruction and vomiting of offensive fluid. The abdomen was greatly distended. There was visible peristalsis. The pulse was rapid. There was no visible tumour.	On Jan. 10th, 1901, a constricting ring of growth was found in the hepatic flexure. Typhlotomy was performed and on Feb. 24th about three inches of the colon with the growth were removed. End-to-end union was effected.	The patient never really rallied from the operation and she died on March 1st, 1901.	At the necropsy th parts were in go apposition at the lin of suture. The growt was a small con stricting ring. Ther were no secondary growths. The cas was seen with Mr. J. N. Hawtin o Leeds.

TABLE SHOWING THE RESULTS OF 14 COLECTOMIES PERFORMED FOR MALIGNANT DISEASE OF THE COLON (*continued*).

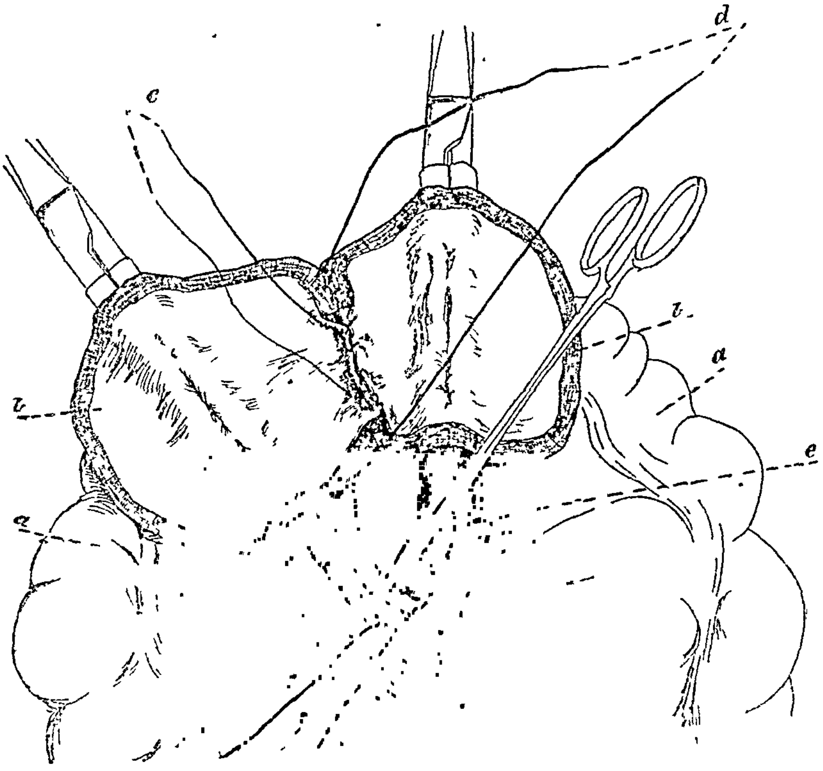
No. of case.	Sex.	Age.	Nature and position of disease.	History.	Signs and symptoms at the time of operation.	Nature and date of operation.	Result.	Remarks.
9	F.	42	Ring of malignant growth in the splenic flexure. No tumour could be felt.	The patient was apparently quite well till three months before, but had always had constipation.	The abdomen was a little distended, with well marked peristalsis. The abdominal wall moved a little with respiration. The patient had vomited everything since August 18th and there had been no passage of either motion or flatus. The pulse was 92 and of a good quality.	On August 24th, 1902, a constricting growth was found with difficulty at the splenic flexure. Typhlotomy was performed. On Oct. 14th the growth from the splenic flexure was excised. End-to-end union was effected.	A good recovery and the patient is now apparently quite well.	The patient was a long time convalescing from the first operation so that the second was delayed more than six weeks. After this she recovered well.
10	F.	60	Malignant stricture in the transverse colon was discovered after the removal of a large adherent ovarian cyst to which all the patient's symptoms were thought to be due.	For some months the patient had been getting large in the body and suffering from pain. She had some constipation which could be relieved with purgatives.	There was an ovarian tumour extending above the umbilicus. There were a good deal of tenderness over this and some constipation. The patient was very feeble.	On April 10th, 1902, the ovarian tumour was removed and at the end of the operation the malignant mass in the transverse colon was discovered and about five inches of the colon were removed. End-to-end union was effected.	The patient never really rallied from the operation and died on the sixth day.	The patient was sent to me by Dr. J. T. Haworth of Filey. She was really too weak for two such extensive operations but I felt at the time that it was worth the risk. The bowels were well opened on the fourth and fifth days by enemata. The patient died from heart failure. A necropsy was not allowed.
11	F.	28	Malignant stricture in the descending colon, with a small circular constricting growth.	The patient had always suffered from constipation and three months before had had a well-marked attack of obstruction which lasted a week.	There were well-marked signs of intestinal obstruction. The abdomen was distended and there was visible peristalsis No tumour could be felt anywhere.	On June 22nd, 1902, the abdomen was opened in the middle line. The intestines were distended and there was well-marked peristalsis in the colon. A narrow ring of growth was found in the middle of the colon. Three inches of colon were removed. End-to-end union was effected.	The patient appeared to go on well for three days, but became worse on the sixth day; the stitching had evidently given way. The abdomen was reopened and death occurred four hours later.	I was asked to see the case with Dr. J. Stewart of Leeds but had to go away two days after the operation. As I was away from Leeds Mr. Walter Thompson kindly saw the case and did the second operation. The parts had entirely separated.
12	M.	65	Large mass involving the cæcum and the ascending colon.	The patient was apparently quite well until two months before the operation. There was some constipation but no obstruction. The patient had got a little thinner. He was working until a few days before the operation.	There was a big mass in the cæcum and ascending colon which could easily be seen and felt, but no obstruction. The patient's general state of health was good.	On Sept. 22nd, 1902, the mass was removed. The divided ends could not be brought into apposition. Anastomosis of the ileum and sigmoid flexure was effected.	Death six days after the operation. The patient became suddenly collapsed two days after operation but improved for a time with saline infusions and strychnia.	The patient was sent to me by Dr. W. L. Hunter of Pudsey. The mass was an enormous growth which had infiltrated the mesentery quite up to its attachment to the abdominal wall. It was attached by inflammatory adhesions to the pylorus and gall-bladder.
13	F.	50	Malignant stricture in the sigmoid flexure.	For two years the patient had been suffering from constipation. Complete obstruction occurred about a week before.	There were well-marked signs of complete intestinal obstruction. The abdomen was greatly distended. There was well-marked visible peristalsis. Vomiting and rapid pulse were present. No tumour could be felt anywhere.	On June 9th, 1899, the abdomen was opened in the middle line. Constricting growth was found in the sigmoid flexure. Another incision was made in the left anterior lumbar region and a loop of bowel with the growth was withdrawn outside and fixed to the incision. The intestine was opened above and drained. A week later the loop of bowel was removed without anæsthetic.	A good recovery and the patient was up and walking about on July 17th. She was well three years after and is, I believe, still living and well.	The case was seen with Dr. G. W. Thompson of Scarborough. There was too much obstruction to think of doing a primary enterectomy. The patient has never cared to have the continuity of the bowel restored, the opening having been quite comfortable.
14	F.	64	Malignant stricture of the sigmoid flexure.	The patient had been suffering from constipation and indigestion since April, 1901, and was taking an aperient daily. Acute obstruction commenced on Sept. 30th, 1901.	The patient was extremely ill with complete obstruction. The abdomen was greatly distended. There were well marked visible peristalsis and distension. Vomiting and rapid pulse were present	On Oct. 5th, 1901, a similar operation was performed to that in Case 13. The second operation was performed on Oct. 25th. The patient was very collapsed after the first operation and stood the second operation badly.	A good recovery ultimately and the patient now appears to be fairly well and without any signs of secondary growth.	The case was seen with Dr. J. McCracken of Coxwold.

paper I have only done colectomy on two others. Both cases were malignant disease of the sigmoid flexure and at the time of the operation had well-marked intestinal obstruction. In the one case a Murphy's button was used and in the other case a bone bobbin; the real cause of the failure was not in the apparatus used, but was due to obstruction present at the time of the operation with fæcal toxæmia. Both patients died. Since then I have adopted the method of which I gave a short account in a paper on intestinal suture which I read before the Leeds and West Riding Medico-Chirurgical Society in October, 1900,[3] and which I now wish to describe more in detail, after which I will refer to the cases of colectomy performed by this method.

OPERATION.

The abdomen having been opened by an incision most suitable for the site of the new growth, if possible the loop of the colon involved in the growth is withdrawn and clamped a good distance above and below the growth (Fig. 1).

FIG. 1.



a, Colon and mesocolon clamped with Doyen's forceps, the blades protected with rubber tubing. b, Divided ends of colon. c, Continuous stitch for mucous membrane. d, Continuous stitch for sero-muscular coats e, Gap in mesentery. , Ligature to unite opposing parts of cut mesenteric edge.

I know of no better clamps than Doyen's pedicle clamps, the blades of which are protected by pieces of india-rubber tubing. The bowel is now divided with a strong pair of scissors and the portion containing the growth, together with a corresponding portion of mesentery with its lymphatics, is removed; the cut ends of the bowel are protected with antiseptic gauze and the vessels in the mesentery, which have been secured with forceps, are ligatured. The divided portion is now thoroughly cleansed with some antiseptic solution. I now remove a circular portion of mucous membrane about from one-eighth to one-quarter of an inch in breadth from both divided ends in order to have a good broad surface of the other coats to bring into apposition. For suturing I prefer a small curved Hagedorn's needle, the eye part of which is no broader than the other portion of the needle; this I use on the flat. Suturing is now commenced, beginning at both cut edges at the mesenteric attachment and the sero-muscular coats are united for half the circumference by means of thin chromic or formaline gut (000). The mucous membrane is now sutured around the whole circumference with the same material, the suture being interrupted by knotting at two or three points; now the remaining half of the sero-muscular coats is united by means of the first suture interrupted by knotting at two or three points of the circumference, so as to prevent the continuous stitch from making the lumen too narrow. The clamps are now removed and the opening in the mesentery is closed; this I do by including opposite points of the gap in the same catgut ligature, three or four ligatures of this kind being generally sufficient to close the opening. This procedure prevents the possibility of perforating a mesenteric vessel which sometimes occurs when a needle and gut are used to suture the cut edges of the mesentery. If possible, the parts operated on are now surrounded with omentum and the abdomen is closed without drainage. The actual suturing can be done in from 10 to 15 minutes. For the last three or four years I have used catgut exclusively for intestinal suture and other abdominal operations—e g., ovariotomy, hysterectomy, &c. If one cannot bring the parts into sufficiently close apposition to secure an end-to-end union then the cut ends of the bowel should be closed by suture and a lateral anastomosis made; this was done in Case 12

If there is complete obstruction, the exact position of which cannot be ascertained, then I prefer opening the abdomen near the middle line, just making an incision long enough to admit the hand and arm, so that there is no escape of the intestines which, if it occurs, is certainly a factor militating against a successful result. With a little practice the hand soon becomes familiar with the feeling of being surrounded by distended bowels and a careful search is made in the usual sites in which malignant disease is most commonly found; beginning at the top of the rectum and working round to the cæcum the malignant growth will in this way be felt. It is best to make the search in this order, for it is in these positions that the malignant growths are less obvious than in the first part of the colon, where the growth can more usually be discovered without making an exploratory incision. Often the bowel is collapsed below the stricture; sometimes it is distended especially if enemata have been given. Having found the growth then the liver is examined to find out if any secondary deposits are present there or elsewhere in the abdomen, for if any secondary deposits are present it will be of no use to make any attempt later to remove the malignant mass. If the patient recovers from the preliminary colotomy and there are no contra-indications, as soon as it is thought that the patient will stand the second operation this is performed in the way just described. I did this in three cases, the patients in two of which (Cases 5 and 7) recovered.

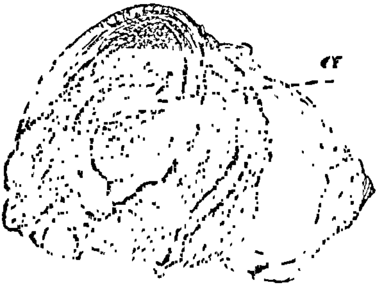
There is another alternative to this plan and that is to withdraw the loop of the bowel with the growth, to fix it in the wound, and subsequently to remove it. This I did in two cases (Cases 13 and 14) in which there was complete obstruction at the time of operation, the obstruction being a small ring of growth in the sigmoid flexure in both cases. The abdomen was first opened in the middle line and the site of the obstruction being discovered another incision was made as for a left anterior lumbar colotomy; a loop of the sigmoid flexure with the growth was withdrawn through the opening and fixed in the wound. The anterior abdominal wound was now closed, the bowel was opened above the growth, and the intestinal contents were drained off by means of a Paul's tube About a fortnight later the portion of bowel and growth were removed without an anæsthetic and both patients made a good recovery and are now living. The first patient (Case 13) was operated on in June, 1899, with Dr. G. W. Thompson of Scarborough, and the second (Case 14) in October, 1901, with Dr. J. McCracken of Coxwold.

---

[3] THE LANCET, June 29th, 1901, p. 1817.

Of the six successful cases of primary colectomy, with end-to-end union, there was practically no obstruction at the time of the operation; of the two fatal cases in Case 10 the malignant stricture in the transverse colon was only discovered and colectomy performed after a very adherent cyst had been removed; the patient, a woman, aged 60 years, was not in a fit condition to stand the dual operation. In Case 11 there was obstruction at the time of the operation; the obstruction appeared to have only produced distension of the colon, the muscular walls of which were apparently in good condition and actively moving. As this was the condition I hoped that I might have succeeded. In this case the better plan would have been to withdraw the loop of sigmoid flexure through an anterior lumbar opening and to treat the case as I did Cases 13 and 14. Although these cases have both permanent colotomy openings they are really very comfortable. I wish to call special attention to Case 4 as it is the earliest condition of malignant disease of the colon which I have had a chance of operating on. After a consultation with Mr. Teale we recommended the patient to submit to an exploratory operation, as we suspected he must have a malignant growth somewhere in the colon. Mr. Michael Teale has kindly made a drawing (Fig. 2) of the portion of bowel removed (I have also to thank him for the other drawing illustrating this paper). It will be seen from this that the growth is of about the size of a florin; it was situated near the mesenteric border and apparently produced the obstruction by tilting on itself, so that the free portion closed the whole lumen and may even have caused a slight intussusception. In the colectomies performed after a preliminary typhlotomy two patients recovered (Cases 5 and 9) and one (Case 8) was fatal, although the patient's condition had greatly improved. At the time of the second operation I believe that a more satisfactory result might have been obtained had I waited for a few weeks longer. Case 12 was a very extensive operation for a man aged 65 years. Cases 13 and 14, considering that they were both operated on during the acute stage of obstruction, are very satisfactory and instructive cases.

FIG. 2.



Portion of bowel from Case 4. *a*, Growth from mesenteric border projecting into the lumen of the bowel.

If the growth is not removeable, or there are secondary growths in addition, then in some cases a lateral anastomosis can be performed; this I did in one case sent me by the late Dr. J. Muncaster of Halifax. The patient was completely relieved of the obstruction and died a few weeks later from extension of the growth. In another case, sent me by Mr. J. W. Roberts of Knayton, I did not do much good; a fæcal fistula formed and the patient died a few weeks after the operation.

In some cases of obstruction, when it is impossible to remove the growth or the presence of secondary deposits makes it inadvisable, a permanent colotomy or typhlotomy can be performed. This I have done several times. In some cases life is prolonged in comparative comfort; other patients are so ill at the time that we see them that typhlotomy is the only thing to be thought of and that sometimes without an anæsthetic. Most of these cases terminate fatally in a few days or weeks from the time of the operation, but sometimes we meet with more encouragement. In a case I operated on with Dr. J. Stewart of Batley, in June, 1901, the patient, a man aged 70 years, had intestinal obstruction due to a constricting malignant mass in the lower part of the sigmoid flexure; it was fixed and I thought it was not a suitable case for removal An anterior lumbar colotomy was performed. The patient is now in very good health and goes down to business every day. Many surgeons can now show examples of excellent results in this field of work, amongst others the papers of Mr. F. M. Caird and Mr. A. E. Barker are valuable contributions to this difficult subject. To study one's cases helps to clear one's views. "It happily so comes to pass that the more clear views we possess, the more do we learn to respect those that are as yet still vague."

In conclusion, I wish to thank the resident surgical officers, my house surgeons, and others who have at all times so kindly helped me, both at the operations and during the after treatment of the cases.

Leeds.

ON PERITOMY FOR DIFFUSE CORNEITIS AND OTHER AFFECTIONS OF THE CORNEA.

BY SIMEON SNELL, F.R.C.S. EDIN.,
OPHTHALMIC SURGEON TO THE ROYAL INFIRMARY, SHEFFIELD;
PROFESSOR OF OPHTHALMOLOGY, UNIVERSITY COLLEGE,
SHEFFIELD.

PERITOMY, or syndectomy as it was sometimes called, was introduced by Dr. Furnari of Paris. He described the operation in the *Gazette Médicale*, 1862. He had, 20 years before this, operated upon some natives of Algiers and had since then repeated the operation in more than 100 cases. Furnari's operation was a much more severe one than is advocated in this article. It has been described as follows: "The patient sits during the operation and the eyelids are kept apart with a speculum. Commencing his incision near the outer canthus Dr. Furnari excised a broad ring of the ocular conjunctiva, extending from the margin of the cornea to within three millimetres (about one-eighth of an inch) of the line where the conjunctiva is reflected from the globe to the inner surface of the eyelids. Symblepharon might ensue if more was taken away. For the purpose of fixing and turning the eyeball during the operation, a flap of conjunctiva is left at the upper margin of the cornea; this is removed last. The subconjunctival tissue must be carefully dissected off so as to expose the surface of the sclera. No trace of cellular tissue or of blood-vessels should be left; any which escape the scissors are to be caught and cut with the sharp hook. The vessels upon the cornea are freely scarified and their ends, if projecting, cut off with scissors."[1] After the subsidence of the bleeding Furnari touched the exposed sclera and ulcerated portions of the cornea with caustic, the vascular only lightly and the transparent portions not at all. The nitrate of silver he applied with a brush which had just before been rubbed upon the solid stick. Furnari stated that a strong irritation but no inflammation followed the operation; the abundant local bleeding apparently acted antiphlogistically. He regarded the operation as indicated in the following conditions: "(1) In the membranous and fleshy pannus; (2) in phlebectasiæ of the conjunctiva and cornea; (3) in simple vascular keratoiditis; (4) in partial vascularities of the cornea; (5) in interlamellar infiltrations of blood or lymph; (6) in corneal lesions resulting from entropium, ectropium, and trichiasis; (7) in staphylomatous conditions of the cornea, consecutive to softening of the latter."[2]

The operation, however, was apparently used chiefly, if not entirely, for the pannus associated with granular lids. Bader in 1863 wrote an article advocating its use in which he spoke of having performed the operation several times, the only untoward results being in those instances in which he had followed Furnari's advice and cauterised the sclera. It appears, moreover, to have been used also a good deal at that time by the various surgeons attached to the Moorfields Hospital. I practised it myself in several cases in my early days for pannus associated with granular lids but never with the added cauterising. The operation, however, fell into disuse for this particular kind of pannus and rightly so, for it merely attacked the corneal affection, which was a secondary one, and left the trachoma untouched. Very properly it has been held that by treating the eyelids by expression or other methods the pannus will clear up as improvement takes place in the trachoma. At the most, therefore, it can only be expected to be of service when associated with other means dealing more directly with the granular lids. Peritomy was revived by the late Mr. H. Bendalack Hewetson. At the annual meeting of the British Medical Association held in Leeds in 1889 he advocated its use in diffuse corneitis and then performed the operation at the Leeds Infirmary on several patients. It is particularly in this form of corneitis that I have myself employed peritomy and in which I wish now to urge its advantages. I have used it extensively during the last four years.

---

[1] Bader: Royal London Ophthalmic Reports, vol. iv., p. 29.
[2] Ibid.

The only recent paper with which I am acquainted advocating peritomy is one read by Mr. T. Pridgin Teale before the Ophthalmological Society in 1901 in which he recommended its use in a variety of conditions—viz., episcleritis, iritis, herpes ophthalmicus, and purulent ophthalmia.

I will now describe my own experience in regard to the operation and the class of cases for which I have performed it. With regard to the operation a general anæsthetic may be given, and indeed it is sometimes required, but in the majority of my instances I have used cocaine. The operation is a brief one and if the cocaine is freely instilled it is usually sufficient. In addition, however, I use adrenalin, instilling it two or three times before commencing the operation. This affords the very great advantages of allowing the operation usually to be a bloodless one, or nearly so, and also the adrenalin seems to increase the anæsthetic effect of the cocaine. A speculum is then inserted and the patient desired to look downwards; a fold of the conjunctiva just beyond the cornea at the upper part is seized with forceps and is then snipped with curved scissors. From this point the conjunctiva is severed all round the cornea at a distance of from two to three millimetres. The portion left adhering to the cornea is next dissected up and removed with scissors. The division of the conjunctiva around the cornea is facilitated by using a pair of scissors having one blade somewhat longer than the other and ending in a bulbed extremity which readily runs underneath the conjunctiva. Recovery is usually quick from the operation, especially in young subjects. For a few days a rim of bare sclerotic is visible, but after the lapse of a very short time there is little indication of any operation having been performed. In a few cases I have performed a partial peritomy opposite any particular portion of the cornea which it was specially desired to affect. This will be further mentioned when I refer to the cases. I have performed peritomy in about 100 cases of diffuse corneitis and my experience has taught me that it is a remedy of particular value. Employed at the earliest stages it, in some instances, seems almost to abort the disease, whilst in others it undoubtedly very materially shortens the long period that such cases usually last. The beneficial effects are often quickly seen in those instances of corneitis which soon show the characteristic salmon-tinted vascularity, particularly at one border of the cornea. For a case in which the salmon-tint vascularity was situated at the upper part of the cornea I did a partial peritomy above. The effect was undoubtedly good, but when the other eye commenced in a similar position I performed a complete peritomy with, I believe, greater advantage. I have seen no evil results from the operation and therefore I should always advocate the complete and not a partial operation. When both eyes are affected I frequently operate on both at the same time.

The results of peritomy in cases of double keratitis have been very satisfactory even when the disease has already been going on for several weeks. I am disposed to think, also, that the cornea recovers its transparency more completely in those cases which have been peritomised than in those in which other methods have been adopted, and thus there is less likelihood of corneal opacities, or should they result they will be less dense than if peritomy had not been performed. For several instances of chronic ulcer of the cornea I have employed peritomy. In one case the benefit was very marked. A man for many years had chronic ulcers, small leashes of vessels running across the cornea to the ulcers. Sometimes he was better, sometimes worse, but the condition had continued for some years. In each eye peritomy was performed with distinct benefit and he was speedily better than he had been for several years. In ulcers, also, which show a tendency to recur peritomy has been done with advantage. A large ulcer on the cornea, to which a leash of vessels ran, was treated with some benefit with the ordinary methods, including the use of the cautery, but still it did not heal. A partial peritomy was done, the conjunctiva being severed and the corneal portion removed corresponding to about from one-third to one-half of the cornea opposite which the ulcer had been situated. The ulcer quickly healed.

Another variety of ulcer of the cornea for which I have performed peritomy with advantage is that superficial kind which occurs in people of middle age and which may spread so much as ultimately to involve the whole of the cornea. Such a case happened last year in a lady, aged about 60 years, in whom an ulcer of this nature began at one edge of the cornea and spread until a superficial ulceration involved practically the whole of it. It was attended with very severe pain and effectually resisted the ordinary applications. Any direct treatment, such as the application of the cautery, was refused by the patient. After six weeks of continuous suffering consent was at last obtained to put her under ether and to perform peritomy. This was accordingly done, and at the same time the ulcerated surface was in some places lightly touched with the cautery. Improvement was immediate and at the end of a week she talked of returning to Scotland and ultimately did so in about ten days. Another class of case in which peritomy may be used with advantage is that which is described as detachment of corneal epithelium. In such an instance which had been continuous for three months I did a peritomy recently with marked success. In my opinion we possess in peritomy a most useful means of treating diffuse corneitis and that in many other corneal affections it is a remedy of great value. In a recent instance of relapsing iritis in a young man peritomy rendered excellent service. I have used it with benefit in other cases, too, of iritis and corneo-iritis.

Sheffield.

THE THERAPEUTIC VALUE OF ALTERNATING CURRENTS APPLIED TO THE ABDOMINAL SYMPATHETIC NERVOUS SYSTEM.[1]

BY SAMUEL SLOAN, M.D. GLASG.,
CONSULTING PHYSICIAN TO THE GLASGOW MATERNITY HOSPITAL AND TO THE GLASGOW SAMARITAN HOSPITAL FOR DISEASES OF WOMEN, ETC.

IN using the term "alternating currents" I am restricting myself to the secondary faradic current and the magneto-electric or sinusoidal; the alternations of high-frequency currents being more properly described as oscillating I shall speak of the former as "alternating" and the latter as "high frequency."

In electro-therapeutics—I may add in general therapeutics—this is the age of electric currents of high potential and high frequency, so much so that currents of comparatively low potential and relatively low frequency are apt to be ignored if not despised. The latter do not appeal to the operator or to the patient as the former do, with their wonderful stage effects, their frequent startling cures, or their fascinating elements of scientific dash. After a year's experience of the high-frequency currents, whilst sanguine as to the future as well as satisfied with the present, I am coming to the conclusion that the success of former days before the advent of high-frequency was at least as real as we can get from the latter. Moreover, the former methods have, in my hands, succeeded where the latter have failed, whilst the high-frequency currents have failed in some cases when a return to the former methods has been followed by gratifying results. Possibly the greater experience of the older electro-therapeutic resources may account for this, "the best administered" being often the best.

These thoughts have led me to review my experience of work in this direction extending over seven years and to bring the results before the members of the British Electro-Therapeutic Society. This work has been faithfully recorded and, as far as possible, scientifically carried out. Thus only can we look for progress and thus only will our work differ from that of the honest charlatan who can often legitimately boast of his success in cases where "the faculty" had failed. He naturally ignores his failures, however, whilst we record them—our aims, let us hope, being nobler than his. Again, if I can add to the testimony in favour of the older methods I may be the means of helping to make the practice of electro-therapeutics more general, because the apparatus can more easily be in the hands of the general practitioner than the more elaborate and more expensive high-frequency installation. I believe —and I speak from a fairly extensive experience—that in the great majority of cases, within certain limits, of course, the kind of electric energy employed is of comparatively little consequence, if only the dose be carefully measured and regulated to suit the nature of the case; and this will differ greatly according to the form of electric energy employed. Thus failure in electro-therapeutics often means maladministration; and this fact should be impressed on the general practitioner who has a curious suspicion of this treatment equalled only by his readiness to recommend that it be tried when he has come to the end of his own resources, leaving his patient usually to find out for himself how to employ the new remedy.

---

[1] A paper read at a meeting of the British Electro Therapeutic Society on April 24th, 1903.

The number of cases on which this paper is based is 67 and the ailments for which the treatment has been used have been atonic dyspepsia, visceral neuroses, neuro-muscular asthenia, asthma, lumbo-pelvic neuritis, persistent sickness with or without diarrhœa, peripheral vaso-motor disturbances (paretic or spasmodic), neurasthenia, uterine atony, and angina pectoris. Amongst the causes or accompanying conditions of these ailments have been the following: actively septic teeth, septic endometritis, influenza, chronic alcoholism, gastric catarrh, intestinal sepsis, epilepsy, obesity, inflammation of the uterus or of the uterine appendages, and anæmia.

It may be asked on what principle this treatment was carried out for so varied a list of affections. To that I can only say—and it may seem an unscientific reason—that it was because I had come to the conclusion from my extensive experience of faradisation of the brain that the electricity acted, when judiciously administered, as a stimulant and tonic to nerve tissue, improving its nutrition, and that, knowing little, if anything, of the pathology of the sympathetic system, but knowing how intimately any disorder there must influence the abdominal viscera and the general circulation, it seemed reasonable, if I could ascertain no cause for the disorder or could not for any reason remove that cause, that whatever improved the tone of the nervous mechanism must improve the patient. This improvement would be temporary if the cause persisted and more or less permanent if the cause were already in abeyance or could be previously removed; and this is exactly how matters have turned out. In practically all the cases drugs had been previously given and all the usual resources of the medical art had been exhausted, whilst during the electric treatment nothing was done, as a rule, which could render the cause of the result doubtful.

Leaving out of consideration the cases in which the treatment was applied once or twice, since no deduction could be drawn from these as to the efficacy of the treatment, as well as those in which the result was doubtful or was not known, and those of my early cases when I had no instrument for measuring the currents, there remain 57 cases. Out of this number there have been 46 cases of complete recovery, or of such a satisfactory result as an efficient holiday would give in favourable circumstances; that is, not what sometimes results from the action of drugs, which result ceases when the administration ceases, but a lasting beneficial effect after cessation of the treatment which brought about the improvement. Where the treatment has been adopted in only one or in a few cases of any particular ailment little can be said of its efficacy in other cases of the same disease or disorder. The oftener this occurs, however, the more reasonable will my contention be regarding the theory of action of this treatment, and even single instances of trial of the treatment if faithfully recorded and collated will at least help towards a correct selection of the cases and assist in bringing about an increase of successes and a decrease of failures.

My failures have been in all 11 and therefore my percentage of successes amounts to 80 when those of doubtful or unrecorded results are omitted. In some of these omissions I have stated that I have left them out because at the time of treatment I had no instrument to measure the current, such an instrument being a *sine quâ non* if the treatment is to be carried out on scientific lines. Some are too recent for me to be able [illegible] the treatment. In others, again, [illegible] in the mind of the patient, been [illegible]ly one or two applications had been employed I have left them out, lest the result might have been a mere coincidence or have followed mainly as a result of suggestion. The accompanying table will show what I mean and what I claim for this treatment:—

TABLE SHOWING THE RESULTS OF ALTERNATING CURRENTS APPLIED IN 67 CASES.

Diseases or disorders.	No. of cases.	Causes or accompanying conditions.										Results.		
		Actively septic teeth.	Septic endometritis.	Influenza.	Chronic alcoholism.	Gastric catarrh.	Intestinal sepsis.	Epilepsy.	Obesity.	Inflammation of uterus or of uterine appendages.	Anæmia.	Successes.	Uncertain.	Failures.
Atonic dyspepsia	6	—	—	1	—	1	—	—	1	1	1	3	2	1
Visceral neuroses	19	—	3	1	2	1	—	—	—	1	1	12	4	3
Neuro-muscular asthenia	17	2	4	2	—	—	—	1	1	2	—	15	1	1
Asthma	1	—	—	—	—	—	—	—	—	—	—	1	—	—
Lumbo-pelvic neuritis	7	—	—	2	—	—	—	1	1	1	—	3	2	2
Persistent sickness with or without diarrhœa ...	6	—	—	1	1	—	1	—	—	—	—	5	—	1
Peripheral vaso motor disturbances—paretic or spasmodic	5	—	2	—	—	—	—	—	—	—	—	5	—	—
Neurasthenia	2	—	—	—	—	—	—	—	—	—	—	—	—	2

Angina pectoris	2	—	—	—	—	—	—	—	—	—	—	1	—	1
Total	67	2	10	7	3	2	1	2	3	5	2	46	10	11

The result of the treatment at the time, especially in very chronic cases, often seemed to me and to my patient unsatisfactory. However, one or more months after and without further treatment, the *vis medicatrix naturæ* having evidently received the necessary fillip from the treatment, the patient is usually gratified by the change in health which may come gradually and as a pleasing surprise after a temporary disappointment.

These results speak for themselves. I have not strained the record so as to make it tell. Rather have I sometimes placed in the list of uncertainties cases that I might have legitimately put amongst the successes. I have endeavoured to be impartial, though you know how difficult it is to refrain from trying to make "a big show." The results are gratifying.

If there is any other treatment which in difficult and chronic cases would give better results I have yet to learn of it.

With reference to the list of diseases or disorders in the table, it must not be concluded that an affection has been defined when it is labeled. The classification, however, is, though not strictly correct, sufficient for practical definition, though some of the cases I had a difficulty in classifying. In the case of the causes or accompanying conditions these were not always simple but often complex; I have, however, endeavoured to classify them as they impressed me at the time.

The following impressions, confirmed by a study of the table, of the kind of case which benefits and the kind in which the treatment is likely to fail may be taken as fairly accurate.

1. Those cases of uncomplicated neuro-muscular asthenia where the cause had ceased or had been removed have proved most amenable to the treatment. By neuro-muscular asthenia I mean neurasthenia minus its psychic elements. 2. Regarding cases of visceral neuroses almost as much can be said. 3. Cases of persistent sickness, some of them of reflex character, have done well under the treatment, the only failure in this list having been one in which the liver was considerably enlarged. 4. The treatment may be relied upon in vaso-motor cases, all of the five cases having been successful. 5. The treatment will be of little avail in neurasthenia. I suspect its only chance here would be after the Weir-Mitchell treatment of it had failed. 6. In cases where inflammatory mischief existed in the pelvic organs the result is not likely to be good. In such cases vaginal electric applications have given the best results. 7. Where septic endometritis exists only a very temporary improvement will follow, although this may be made a permanent one if the treatment is resorted to after curettage has removed the septic condition from the uterus. 8. Epileptics are likely to derive no benefit from the treatment. I had two cases of angina with no apparent evidence of organic disease. As the table shows, recovery ensued in one, but the treatment in the other appeared to have no influence or rather seemed to make the symptoms worse. Perhaps in the successful case the success was due to the anterior electrode having been placed during part of the treatment over the cardiac region and in the case of failure I suspect the dose given was too large. This patient had a somewhat alarming collapse during one of the applications.

The title of my paper shows that these favourable results, where such has been the case, have, in my opinion, arisen from the action of the currents on the sympathetic system of the abdomen. You may, therefore, expect me to say why I think this has been so.

1. There are anatomical reasons, the electrodes, as I shall afterwards explain, being placed one behind the origins of the splanchnic nerves and the other in front of the prevertebral plexuses of nerve fibres and ganglionic cells of the abdominal sympathetic system.

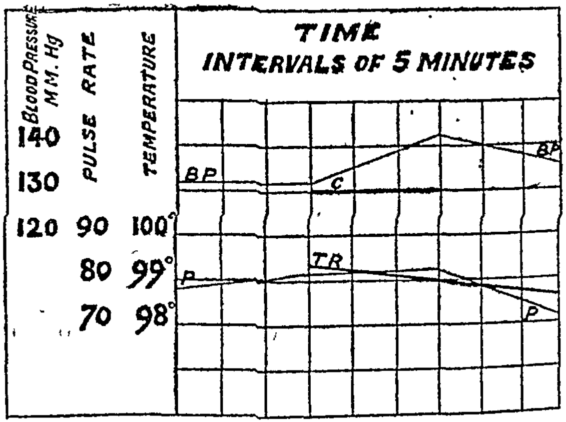
2. Whilst Professor d'Arsonval points out that no influence is made on nerves by currents having a frequency of over 5000 alternations per second, it must be otherwise with these currents we are now considering, since they have as low a frequency as about 40 per second. Here the fibres and cells of the nerve are probably influenced by something of the nature of rhythmic molecular massage or by vibrations of such frequency as they can respond to.

3. Whereas in high-frequency currents the main influence of the currents is on the skin, with these we are considering the easiest path is by the soft deeper tracks.

4. Whilst, as I have elsewhere pointed out, in faradisation of the head even therapeutic doses cause more or less psychic phenomena, showing that there is faradisation of the brain as well as of the scalp, the effect on the other hand of dorso-abdominal faradisation is to produce exactly what physiologists point out as caused by stimulation of the sympathetic system—namely, exhaustion, for after almost every application of the current there follows decided, often great, sometimes profound, exhaustion. This, however, I have noticed, is within—it must be—certain limits a favourable sign if followed by a sufficient rest, for after a proper amount of rest there follows the opposite condition of a comfortable sense of vigour and well-being, but only when the rest obtained is proportioned to the exhaustion felt. I may add here that I have never known a patient in the least degree afterwards the worse for this treatment. Query: Is this constant after-exhaustion not due to sudden absorption of toxins from the alimentary canal, caused by stimulation of absorbing power due to stimulation of the ganglia of the sympathetic system? The fact that this period of exhaustion and its amount diminish as the case favourably progresses may be due to the amount of toxins diminishing by improved nutrition of the digestive organs, for the dose of the current is generally increased later in the course of the treatment and then with generally slight fatigue only.

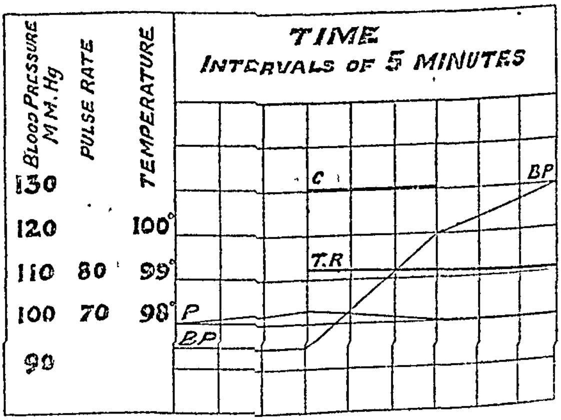
5. I have made some experiments on blood pressure, pulse, and temperatures before and after the applications, taking care to employ control tests at the same time. These show a practically constant rise of from five to 30 or more units in the blood pressure, without, as a rule, any change in the pulse-rate, but with a slight fall of the temperature in the mouth and in the rectum. If there is a fall of the pulse-rate there is less increase of the blood pressure, but still some. This shows that the rise of blood pressure is not due to an increase of cardiac rate, which is often rather considerably reduced, so I infer that it is due to a mild stimulation of the sympathetic system, causing a diminished relaxation of the arterioles of the splanchnic area. This, I take it, is also evidence in favour of the direct action of the current on the sympathetic ganglia, since a paresis of these ganglia causes, pathologists tell us, a congestion of the abdominal organs. I submit charts of two of the cases which will explain, perhaps, more clearly what results I obtained.

CHART 1.



B P, blood pressure. C, current, the amount being four milliampères. P, pulse. TR, temperature.

CHART 2.



B P, blood pressure. C, current, the amount being four milliampères. P, pulse. TR, temperature.

6. As a negative reason, I feel sure that the element of suggestion may be eliminated for the following reasons: (a) No rash promise is made to the patient beforehand; (b) the current is so weak, compared with the large size of the electrodes, that the patient often complains of getting nothing at all; (c) the after-exhaustion is certainly an argument against suggestion; (d) some of the experiments, especially two of them which were made on medical men, were on those little likely to be influenced by suggestion; and (e) there has been an absence of early or sudden

benefit; this having been rather slow and somewhat delayed, especially in finally successful cases.

I need not dwell much on the method of administering the currents. Two large moist clay electrodes, warmed, are applied. The one, about 9 inches by 6 inches, is placed, attached to the positive pole, between the shoulder-blades; the other, attached to the negative pole and measuring 9 inches by 10 inches, is placed over the abdomen, especially over the epigastric region. The current is from a secondary coil of about 8000 turns of fine wire and the dose is carefully measured by my faradimeter which I exhibited before the British Electro-Therapeutic Society in 1902.[2] When the sinusoidal current is used the alternations are about 1800 per minute, the voltage being much the same as that of the secondary coil. The dose at the first *séance* is from 2 to 3 milliampères. As the case progresses this is raised till a dose of 7 or at most 8 milliampères is administered. The *séance* lasts each time for 15 minutes. Should the coil have a larger number of turns on it than 8000 the current may be given in larger doses than those stated. If a smaller coil is used a smaller dose must be given. The patient, at the early sittings especially, should be made to rest for at least 15 minutes before going home and should then go to bed for an hour or longer, or recline for that time on a sofa. The applications are given every second, third, or fourth day; and the number which usually suffices is from six to eight. If a longer course seems to be required on account of the chronic nature of the complaint a gradually decreasing size of coil should be used and the former dose maintained.

The following few notes of three illustrative cases may prove interesting as a finish to my remarks.

CASE 1.—The patient was a single woman, aged about 40 years. Till a few years ago she had been a person of great mental capacity and with the normal amount of self-control. The abrupt news, however, of her mother's sudden death quite altered her nature and she gradually became a chronic alcoholic. When first attended by me two years [illegible] she volunteered the remark that she was less easily worried or fatigued and that she felt less craving for the brandy. Improvement was steady. The treatment, however, was kept up for several months, at intervals of about a week, at her own request, as she said that she was persuaded that if the treatment stopped the desire for alcohol would again become irresistible. Recently she informed me that for eight years she had had agonising pains every night for which she had always to remove her stays in the early part of the evening and that she had had no distress of this sort during the past year. The mere presence now of a lady companion suffices to enable her to maintain almost a normal amount of self-control.

CASE 2.—This case, though one probably of malignant tumour of the abdomen which has since ended fatally, was [illegible] this treatment. It was that [illegible] years, resident in the south of [illegible] of mine in Glasgow. When he came to me in August, 1901, I was shocked at the change in his appearance though I had heard that he was considered to be dying. His weight about four years previously had been 12 stones 5 pounds; it was at his first visit to me 7 stones 13 pounds. His principal complaints were of frequent and copious vomiting with constant diarrhœa, the motions being watery, slimy, and putrid. He had become exceedingly nervous and irritable, his natural temperament having been a placid and amiable one. The abdomen was full and tympanitic throughout, but no fluid could be detected nor was there any evidence of a tumour. As he had been frequently examined by various medical men and no evidence of organic disease had been detected I hoped that what was evidently mainly a paresis of the abdominal sympathetic system might be the primary and not the secondary condition. On this hypothesis I suggested electric treatment. He was so ill and the case seemed so hopeless that I proposed a fortnight's trial only of the treatment. Of the five medical men who had seen him no one had spoken of treatment by electricity. After six applications the improvement was so great that no question as to its beneficial influence had to be entertained. At the end of four weeks I note in the patient's own words as follows: "Decided improvement, don't feel the same at all as I was when I first came to you." I sent him now to Yorkshire for a change from city life. During that month he was only once sick and that was after eating cheese and he had gained half a stone in weight. The electric treatment was resumed and continued for two months. He then went home feeling better than for two years. Six weeks later he wrote as follows "My improvement is still maintained. I feel better than I have been for the last four years." During the following summer he gradually lost in health; fluid was detected in the abdominal cavity and the suspicion of tumour, though never confirmed, seemed to have been strong in the mind of his medical attendant. He died in October, 1902. There was no post-mortem examination.

CASE 3.—This patient was married and was about 30 years of age. She was of good constitution, though with slight glycosuria during her pregnancies. During the summer of 1901 she had an attack of influenza when in London. Severe neuro-muscular asthenia supervened and in spite of medicinal treatment by several medical men and a residence in Homburg during the autumn this condition persisted till the following April when I decided to stop all medicinal treatment, which seemed only to upset her, and to try dorso-abdominal faradisation. The first dose was 3 milliampères, the patient being quite unconscious of the presence of the current. Severe fatigue followed, lasting for 36 hours. The dose at the next visit was reduced to 2 milliampères and little fatigue followed. Gradually the quantity was increased up to 5 milliampères. No fatigue whatever followed. Three weeks from the first application the note is: "Less depressed, digestion perfect, in every way much better." She became pregnant in June following, passed through the period of pregnancy in excellent health, was confined recently, and has made a perfect and an unusually quick recovery. She informed me a few days ago that she had had no return of the nervous exhaustion.

Glasgow.

SUCCESSFUL REMOVAL OF MORE THAN THREE-QUARTERS OF THE STOMACH FOR CANCER, WITH GASTRO-JEJUNOSTOMY.

BY J. LYNN THOMAS, C.B., F.R.C.S. ENG.,
SURGEON TO THE CARDIFF INFIRMARY; CONSULTING SURGEON TO THE "HAMADRYAD" HOSPITAL, PORTH HOSPITAL, BRIDGEND HOSPITAL, AND CARDIFF PROVIDENT DISPENSARY.

DURING the year 1902 I opened the abdomen five times for carcinoma *of the stomach, prejudging from physical signs* that the growth was removeable, but in only one of my cases was it possible to do anything more than the palliative treatment of short-circuiting. In four of the cases, after inspecting the local growth, it was evident that conditions existed of which one had no detectable external physical *signs and which at once negatived the* projected removal of the growth; these unforeseen and unfortunate conditions were: (1) secondary growths in the liver, (2) infection of the glands in the transverse mesocolon and (3) along the vertebral column. As regards the symptoms which guide one in forming an opinion as to the practicability of the performance of a pylorectomy or of a partial gastrectomy, mobility of the growth is one of the most important and, as a rule, if one cannot shift the position of the gastric growth by distension of the stomach with air, it will be found upon exploration to be inoperable. The non-observance of this fact is one of the causes of failure in the performance of the operation. Weyman's syringe is perhaps the best instrument for inflating the stomach in order to demonstrate the mobility of a gastric growth and also of showing the size and shape of the stomach itself, but an ordinary small pair of bellows fixed on to a rubber stomach-tube answers the purpose equally well, as the surgeon has the air inlet valve under perfect control and can convert it into an outlet valve when necessary in a second by pushing a finger under it. The situation of a pyloric growth is very variable; it may be situated to the left of the middle line, in the middle line above,

BRADFORD ROYAL INFIRMARY.

THREE CASES OF PERFORATED GASTRIC ULCER.

(Under the care of Dr. C. F. M. ALTHORP.)

CASE 1.—An unmarried woman, aged 23 years, was admitted to the Bradford Royal Infirmary under the care of Dr. C. F. M. Althorp on March 13th, 1902 For seven years she had had pain and vomiting after food. 32 hours before admission, whilst at work, the patient was suddenly seized with acute pain in the abdomen followed by symptoms of collapse. When she was seen at the infirmary the pulse was 102 and the temperature was normal. She complained of abdominal pain. The abdomen was distended, with rigid walls, and the liver dulness was absent. Perforated gastric ulcer was diagnosed and without delay the abdomen was opened in the middle line above the umbilicus. Gas escaped on opening the peritoneal cavity and lymph was seen on the anterior and upper walls of the stomach. Old adhesions fixed the stomach and great difficulty was experienced in obtaining a view of the perforation, which was of about the size of a threepenny piece and was situated in the centre of a large ulcer near the cardiac end of the stomach. A large collection of escaped contents of the stomach had already formed a perigastric abscess. Owing to the position of the perforation and because the stomach was fixed by adhesions it appeared impossible to close the opening by stitches. Several silk sutures were introduced, but they tore out on an attempt being made to tie them. It was therefore decided to trust to gauze packing, especially since the general peritoneal cavity was cut off by recent adhesions. The infected area was mopped dry and gauze was packed around the perforation. The patient stood the operation well and appeared to progress nicely for ten days. The gauze packing was removed on the third day, the cavity was mopped dry, and fresh gauze was introduced daily. The discharge was extremely offensive. Rectal feeding was employed for nine days, then small quantities of peptonised milk were given by the mouth. On the tenth day the patient began to cough and she expectorated a small quantity of offensive pus. There were found to be signs of consolidation at the base of the left lung. An exploring needle introduced into the dull area withdrew a little pus. An anæsthetic was given and the left pleural cavity was explored. There was no pus in the pleura or collection below the diaphragm. The lung was solid. The patient died on the following day from pneumonia.

Necropsy.—The post-mortem examination revealed hourglass contraction of the stomach caused by a large ulcer in the centre of which was the perforation. Opposite to the ulcer there was an opening in the diaphragm and here the base of the lung was adherent. There were no empyema and no subdiaphragmatic abscess. The lower lobe of the left lung was solid and near the base was a small septic abscess.

CASE 2—On Jan. 23rd, 1903, a man, aged 23 years, whilst at work was suddenly attacked with severe abdominal pain followed by symptoms of collapse. Two months previously he had vomited a pint of blood and had since been under treatment for gastric symptoms. Eight hours after perforation he was seen at the Bradford Royal Infirmary. Being under the influence of morphia he had no pain; his pulse was 84 and the temperature was normal. Ether was given and on opening the abdomen gas escaped and contents of the stomach were seen spread over the anterior surface of the stomach. A large perforation was seen on the lesser curvature of the stomach near its cardiac end deep down under the arch of the diaphragm. Adhesions were forming between the stomach and liver and a line of lymph cut off the area of perforation in a downward direction. The perforation was the centre of a large ulcer which had by its contraction given rise to a condition of hour-glass stomach and had fixed the organ posteriorly by adhesions. The stomach could not be withdrawn into the abdominal wound. The stitching therefore had to be done within the abdomen. The stomach tissue around the perforation was extremely rotten and the stitches tore out. A Halstead suture of thick silk passed wide of the perforation drew the edges of the opening together. The area of the perforation and of the ulcer was further closed in by bringing together a fold of healthy stomach wall from each side by means of a row of interrupted silk sutures. A fold of omentum was stitched over the line of union The peritoneal cavity was washed out with hot saline fluid and the abdominal wound was closed without a drain. The after progress was very satisfactory, except that at the end of the first week an abscess formed in the left flank and required incision and drainage. This appeared to indicate that the left kidney pouch had not been efficiently washed out at the time of operation. Two months after the operation the patient was quite well and was taking ordinary light diet without discomfort.

CASE 3.—An unmarried woman, aged 27 years, was admitted into the Bradford Royal Infirmary on March 14th, 1902, with signs of a perforated gastric ulcer. For five years she had had symptoms of indigestion. The present attack came on in the street soon after a meal—there being severe pain in the abdomen and vomiting. When seen at the infirmary eight hours after the perforation there were abdominal pain and rigidity. The pulse was 112 and the temperature was normal. The abdomen was opened in the middle line and gas and contents of the stomach were at once noted. The extravasated fluid was mopped up both to the right and to the left, but no perforation was found on the anterior surface, the lesser curvature, or the cardiac end of the stomach. The transverse colon was drawn upwards, an opening was made in the transverse mesocolon, and the stomach was drawn out of the lesser sac on the surface of the abdomen. Very little fluid was present in the lesser sac. About the middle of the posterior surface of the stomach was an ulcer of the size of a sixpence and in the centre of this was a small rounded perforation. The opening was closed by two layers of silk sutures. The stomach was returned to the lesser sac and the opening in the transverse mesocolon was closed with a continuous catgut stitch. The pelvis and right kidney pouch were full of turbid contents of the stomach which were removed partly by mopping with sponges and also by flushing out with hot saline solution A glass drainage-tube was introduced into the pelvis through a suprapubic opening and the right kidney pouch was drained by means of a split rubber tube with a gauze wick inside. The abdominal wound was closed by silkworm-gut sutures passing through all the layers. The patient was very collapsed at the end of the operation and required hypodermic injections of strychnine and saline fluid by the rectum. On the fourth day the drainage-tubes were removed and at the end of a fortnight the patient was taking a fluid diet by the mouth. Some symptoms of lung complication appeared in the third week but they fortunately cleared up and she made a slow convalescence.

Remarks by Dr. ALTHORP.—In Cases 1 and 2 the perforations were in hour-glass stomachs caused by large ulcers near the cardiac end. In Case 1 it was found to be impossible to suture the opening, gauze packing being used; in Case 2 the perforation was closed with great difficulty and no drainage was employed. In both of these cases the stomach was fixed posteriorly and could not be drawn into the abdominal wound The perforation in Case 3 was in the posterior wall of the stomach, access being obtained through an opening in the transverse mesocolon.

Perforation of the posterior wall of the stomach is rare (9 per cent., Robson) and perhaps an easier way of getting access to the lesser sac in Case 3 would have been by tearing through the great omentum below the greater curvature of the stomach. The extravasated fluid had in this case passed out of the foramen of Winslow into the right kidney pouch and down into the pelvis and, in fact, had spread all over the peritoneal cavity. There was in consequence a good deal of shock. The presence of hour-glass contraction of the stomach in Cases 1 and 2 made the operation very difficult on account of the stomach being fixed and the out-of-the way position of the perforations. Drainage was employed in Cases 1 and 3. In Case 1, although the length of time between perforation and operation (32 hours) made the prognosis almost hopeless, the gauze drainage

acted very well. In Case 3
hours after perforation, ye
account of the extravasation
of the stomach all over the
of perfo case of perforated
gastric hour-glass stomach
is one of the patient at the
time of operation. In Case 2 the cardiac compartment was very small and the stomach was so fixed behind that great difficulty would have been experienced in performing an anastomosis even had other circumstances been favourable.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

An Inquiry into the Phenomena attending Death from Drowning and the Means of Promoting Resuscitation in the Apparently Drowned.

A MEETING of this society was held on May 26th, Mr. ALFRED WILLETT, the President, being in the chair.

The PRESIDENT said that the committee for the investigation of the phenomena attending death from drowning had been appointed by the society in 1892. During the earlier part of the last century the method introduced by Dr. Marshall Hall for resuscitating the apparently drowned was that which was universally adopted, but towards the end of the "fifties" Dr. Silvester's method was advocated and it was thought to be more efficacious. A committee was formed for the investigation of the subject and reported in favour of Dr. Silvester's method in 1862 The method had since then been almost universally adopted, but there were those who had criticised, and still differed from, the results of the committee and it was therefore in 1892 that the society formed a fresh scientific committee further to investigate the subject and members would hear that night from Professor Schafer the report of that committee

Professor E A. SCHÄFER said that in considering the manner in which the question which was placed before the committee might best be solved it became clear that it would be necessary for the inquiry to be pursued along two different lines—the one having for its object the determination of the most efficient and most convenient mode or modes of carrying on artificial respiration in the human subject, and the other, the investigation of the physiological phenomena which attended asphyxia produced by the introduction of water in place of air into the lungs, as well as the phenomena which accompanied recovery in apparent death by drowning. This branch of the inquiry could, of course, only be conducted upon animals; and for various reasons dogs were by far the most suitable subjects upon which to carry out such an investigation. As was the case, therefore, with the report submitted by a previous committee of the society and published in the Transactions for 1862, the report consisted, so far as the experiments recorded were concerned, of two parts —one dealing with physiological experiments upon dogs and the other of experiments designed to measure the amount of air which could be taken into or forced out of the lungs in man by various methods of artificial respiration. Experiments to determine the amount of air which could be taken into or forced out from the lungs by various methods of artificial respiration were carried out by experiments of a similar character to those which were instituted by the 1862 committee, which made a number of observations upon the dead body with this object. But the method generally employed—that, namely, of tying a tube into the trachea, this tube being connected with a balanced bell-jar—was open to the obvious objection that no such operative procedure as this could well be used in cases of apparent drowning In such cases, moreover, there were factors connected with the

the pharynx and which also had been supposed to cause the epiglottis to fold over the superior aperture of the larynx. On these grounds it seemed to the committee of importance to determine, if possible, the question of the amount of air passed into and out of the lungs (under different methods and conditions of artificial respiration) with preservation of the natural channels through the nostrils and mouth. In order to effect this result the committee employed a face-piece or mask, with tubular rubber margin which could be fitted so as to be air-tight, with the aid of vaseline, over the mouth and nostrils, and this mask was connected either to a spirometer or to a balanced bell-jar similar to that used by the 1862 committee, with its mouth dipping under water, and so arranged that it would move up or down according as it contained more or less air. The difficulty of experimenting upon the dead body was, however, so great that it occurred to the committee that it might be feasible to carry out the inquiry upon the living subject, the conditions necessary being that the subject should remain completely passive without making any attempt at natural respiration for the short period of time during which the experiment might last, and that he should not, by involuntary closure of the glottis, prevent the free passage of air into, or out of, the lungs. The first of these conditions could be readily fulfilled if the subject, immediately prior to the experiment, made several deep respirations, for he thereby rendered himself temporarily apnœic and the *besoin de respirer* was absent. In these circumstances it was by no means difficult to perform artificial respiration for a short time without any resistance on the part of the subject and without his making any spontaneous movements of respiration. The second condition necessary for success—the maintaining an open glottis—was at first more difficult. The results of these experiments showed that by nearly every method used a greater volume than the normal tidal air entered the lungs The methods which might be employed in artificial respiration in man were of three kinds—viz.: (1) those in which air was drawn into the lungs by increasing the capacity of the thorax (which could only be done artificially by raising the ribs); (2) those by which air was forced out of the thorax by direct compression of its walls or indirectly by compression of the abdomen; and (3) those by which air was driven by means of a pump or bellows through the air passages into the lungs. It was obvious that both kinds of methods enumerated under

exerted upon the chest walls; this was, in fact, the method which was generally employed and was that recommended by Dr. Silvester. There was one serious danger to which the pressure methods were liable—viz, that of causing injury to the internal organs. The greatest danger was to the liver, which in all cases of drowning, and of asphyxia in general, was enormously congested and enlarged. In these circumstances a very little excess of pressure—especially if it were applied to the lower part of the chest or the abdomen—was sufficient to produce rupture of the liver with concomitant extravasation of blood into the peritoneal cavity. Some of the experiments upon dogs illustrated the reality of this danger, and it was not an unknown experience that in cases of death from an overdose of chloroform in the human subject, in which various methods of artificial respiration—and these often included forcible compression of the lower part of the thorax or of the abdomen—had been resorted to in attempts at resuscitation, it had been found post mortem that the peritoneal cavity contained a large effusion of blood, resulting from rupture of the liver. The methods of artificial respiration which had been tested were: (1) simple traction (and relaxation) by both arms, the subject being in the supine position; (2) traction by both arms with alternating pressure upon the thorax, supine position; (3) intermittent pressure on the thorax, supine position; (4) simple traction (and relaxation) of both arms, the subject being in the prone position; (5) traction by both arms with alternating pressure upon the back of the thorax, prone position: (6) intermittent pressure on the back of the
thorax, one arm only, the sub-
ject lyi with the opposite arm
underne ction by one arm with
alternating pressure upon the thorax, lateral position; (9) intermittent pressure on the thorax, lateral position; and (10) rolling the subject alternately from the lateral or latero-supine to the prone position with alternating pressure upon the back of the thorax. All the methods employed were competent to effect a sufficient exchange of air to maintain the oxygenation of the blood. Very few of the methods gave results less than the volume of the tidal air of the individual. The least amounts were those yielded by the traction method pure and simple,

but the combination of this with alternating pressure gave results which were in some instances much larger than, and in the others very nearly, if not quite, as large as, the amount of tidal air. The marked effect of pressure in assisting the output and subsequent elastic intake of air was particularly well seen in the case of the younger subjects, and this was doubtless due to the greater mobility in them of the thoracic walls. It further appeared that the prone position was advantageous in assisting the effects of pressure, probably because pressure applied to the back became more evenly distributed over the thorax and abdomen. It appeared to the committee that both this method and the even more simple method of rhythmic pressure upon the back with the subject placed in the prone position, should occupy a prominent place in all recommendations made with the view of the resuscitation of the apparently drowned. One of the most striking results shown in the series of experiments on dogs drowned in fresh water was that of the complete disappearance of the water which was taken into the lungs, even in cases in which artificial respiration was not followed by recovery. The actual amounts which were absorbed had been found to be very variable (from 75 to 690 cubic centimetres). This no doubt depended somewhat upon the size of the dog used, but it probably depended more upon the character of the respirations, especially those at the beginning of the immersion. Another striking fact which came out in these experiments was the great length of time during which immersion might last and yet be followed, with efficient artificial respiration, by complete recovery. Several of the experiments illustrated this point. In one case the immersion lasted nearly eight minutes without a fatal result. In other instances a much shorter immersion was followed by death in spite of artificial respiration, and even in two instances in spite of the fact that the natural respirations were recovered. The reason for the failure of recovery—when it was not due, as seemed to be the case in certain instances, to early complete failure of the heart—appeared to have been due to deficient aeration of the blood by the respiratory movements. The results with sea-water were, on the whole, similar in character to those with fresh water, but there were certain points of difference So far as these experiments went it would seem that there was, as a rule, less absorption of water by the lungs. This was, of course, to be expected, seeing that the osmotic force of sea-water was higher than that of the blood. Indeed, in one experiment this showed itself by the fact that a larger amount of fluid was returned from the air passages than had been taken in and the excess must have come either from the blood or from other fluids of the animal body. Since one of the most marked physiological symptoms of death by asphyxia from drowning—as in other forms of asphyxia—was the extreme lowering of blood pressure owing to paralysis of the vaso-motor system, it was hoped that such a drug as suprarenal extract might, by antagonising this symptom, produce, in association with artificial respiration, rapid recovery; the more so because this drug was known also to increase the force and rate of the heart's action. But it was obvious that it would only act if there were some sort of circulation going on to promote its absorption and to carry it to the peripheral vessels; and even then it could only produce permanent benefit if the artificial respirations were efficiently promoting the aeration of the blood, since as long as the venous condition of the blood continued the paralysis of the vessels and heart could not be more than quite temporarily relieved. This was, in fact, what was found to occur, for in cases in which, owing to froth in the bronchi, the diffusion of the oxygen of the inspired air into the alveoli was interfered with, or in which, from any other cause, the artificial respiration was inefficient, the result of intrapulmonary or intracardiac injection of adrenalin had only a quite temporary effect—the blood pressure rising and the pulse improving for a short time—to give place again to paralysis of vessels and heart and at the best only deferring the fatal result for a brief period.

Dr. H. R. SILVESTER said that he should confine his remarks to discussing the most convenient and efficient mode of carrying out artificial respiration. He regretted that the committee of inquiry had not used the same method for estimating the amount of air that could be introduced into the lungs as the committee of 1862, for he considered that no satisfactory results could be obtained by estimating the amount of air passing through the upper air passages, for some portion of the air would tend to find its way into the stomach and thus prevent any accurate comparison. Another serious objection to the face mask method was that air from the stomach was liable to pass into the spirometer. He thought that the rolling method had the additional disadvantage that the contents of the stomach were liable to get discharged into the pharynx and so into the air passages Dr. Silvester pointed out the importance while using traction to have the body on an inclined plane and even in some cases to tie the feet. He considered that the conclusions of the present committee were based on insufficient evidence

Dr. R. L. BOWLES said that the report of the present committee confirmed the report of the committee of 1862, which showed that sufficient air for the maintenance of life could be introduced by alternate compression and relaxation of the chest wall and by means of movements of the arms. The present committee had experienced the same difficulty in estimating the amount of air capable of being taken in and driven out of the thorax by artificial respiration in carrying out the experiments on the dead body as the committee of 1862, but by well working the muscles the rigor mortis of the body might be overcome and the chest could be rendered more or less elastic before beginning the experiment. He considered that the falling back of the tongue and the collection of mucus in the pharynx were the greatest hindrances to artificial respiration and that while the body was in the supine position these difficulties could not easily be overcome, whereas if the body were in the prone position neither of these difficulties could occur. He thought that it was important that the simplest and most efficient method of resuscitation of the apparently drowned should be given to the public and therefore he strongly urged that the prone and not the supine position should be used. He doubted if experiments on dogs were of much value, for the conditions present in the dog with regard to habits and position differed so entirely from those of man that the conditions could hardly be made comparable. The condition of the lungs found in the dogs drowned experimentally did not correspond with that which was found in man drowned, for in the latter case a considerable amount of water was usually found in the lungs. He thought that the danger of rupture of the liver was a real one and was another reason for not employing pressure during artificial respiration. In conclusion he said that both the Marshall Hall and Silvester methods had been shown to be capable of introducing air into the lungs, but that the public should be taught to use only one and that the Marshall Hall method.

Lieutenant-Colonel C. R. WOODS said that the first thing to do in resuscitating the apparently drowned was to get rid of the water from the lungs and this was most effectively done by turning the patient into the prone position. He thought that with a heavy body the rolling method had some advantage but that the Silvester method could be more readily carried out. He thought that too little pressure was often employed in expelling the air from the chest.

Dr. F. W. HEWITT called attention to the fact that there was often a considerable amount of muscular spasm of the upper air passages during the administration of an anæsthetic which might produce asphyxia and this was not removed even when the trachea was opened. He thought that the method of inflation of the lungs was of great service and that the method might be elaborated.

Dr. M. S. PEMBREY said that it did not seem to him that the absolute quantity of air made to enter the chest during artificial respiration was of much importance, for a few extra respirations made up for any deficiency in the actual amount at each inflation. The influence of the nervous system was a matter of great importance in man. The amount of water which the lungs would rapidly absorb was very considerable. Dr. Pembrey suggested that the method of absorption might be traced by colouring the water with carmine.

Professor SCHÄFER replied.

CLINICAL SOCIETY OF LONDON.

Ileo-cæcal Invagination by a Meckel's Diverticulum.—Sequel to a Case previously shown as one of Congenital Morbus Cordis.—A Case of Great Dilatation of the Heart.—Election of Officers

A MEETING of this society was held on May 22nd, Mr. HOWARD MARSH, the President, being in the chair.

Dr. J. P. ZUM BUSCH read a paper on a case of Ileo-cæcal Invagination by a Meckel's Diverticulum. The patient was a man, aged 21 years, an acrobat by occupation. He had suffered for several years from abdominal symptoms pointing to an intestinal growth. The condition became suddenly worse after a heavy strain during muscular exertion. Sickness and vomiting, the passage of blood by the anus, and the appearance of a quickly growing swelling in the ileo-cæcal region led to the diagnosis of invagination produced by intestinal polypus and necessitated an immediate operation. The abdomen having been opened, an ileo-cæcal invagination was found and with great difficulty reduced. This invagination was, however, only secondary to a primary invagination of a Meckel's diverticulum into the ileum. Extensive gangrene of the intestine rendered the excision of the whole invaginated portion (about three feet) necessary. Side-to-side anastomosis was performed and an uneventful recovery ensued. The condition described was a very rare one, as only 15 cases of invagination of a Meckel's diverticulum had been published; in 12 of these a secondary invagination of ileum into ileum or ileum into cæcum occurred. The prognosis of this condition seemed to be exceedingly bad, as in only one case had the patient recovered after excision of the gangrenous intestine. In that case, which was published by Brunner, it was not absolutely certain whether the inverted part was really a Meckel's diverticulum or whether it was an invagination produced by an accessory pancreas.—Mr. W. G. Spencer referred to the small lipomata found in the pancreas [illegible] formed the starting-point of c[illegible] Corner described the two [illegible]ticulum became invaginated. In some cases the invagination might start at the apex of the diverticulum and these mostly ran a chronic course. But in other cases the diverticulum became invaginated and the small intestine contracted upon it; the symptoms in these circumstances became acute.—Dr. zum Busch replied.

Dr. Percy Kidd narrated the sequel to a case previously exhibited before the society as one of Congenital Cardiac Disease. The patient was a girl, aged 23 years, who was shown before the society in February, 1901.[1] The case was regarded by nearly all those who saw it at that time as one of congenital morbus cordis. There were marked dilatation and hypertrophy of the right side of the heart and a loud second sound more marked over the pulmonary area. The patient died six months later and very extensive endarteritis was found to involve the pulmonary artery and its branches, though the pulmonary valves themselves were healthy. The lungs were engorged and the right side of the heart was much enlarged in consequence of the disease of the pulmonary artery. The history suggested that the arterial disease originated during intra-uterine life.—Dr. P. Horton-Smith had made the macroscopic and microscopic examination of this case. There was extensive and advanced chronic endarteritis in the pulmonary artery and its branches but limited to the pulmonary system of vessels. There was no emphysema of the lungs. The cause was very obscure; there was no history of gout, lead, or alcohol.—Dr. H. Batty Shaw remarked on the occurrence of a diastolic murmur on the right side of the sternum in this case. Such murmurs occurred in association with mitral disease, but it was probably generally due to leakage of the pulmonary valves. Dr. Kidd's case helped to substantiate this view.—Mr. Spencer discussed the occlusion of the duct of Botalli and the hypogastric arteries in relation to lesions of the kind under discussion.—Dr. F. Parkes Weber, referring to the diastolic murmur, asked whether there was any relative dilatation of the right auricle, because relative tricuspid stenosis might produce a diastolic murmur.—Sir Hugh R. Beevor referred to a case in which both pericarditis and aortic disease were suspected but dilatation of the right heart alone was found after death.—Dr. W. Ewart regarded diastolic murmurs such as that in this case as of mitral regurgitant origin and not arising in the pulmonary valve. He could hardly believe that the lesion, which was evidently a progressive one, in Dr. Kidd's case was of congenital origin though its cause was evidently very obscure.—Dr. Kidd, in replying, thought that the lesion must have arisen in intra-uterine life and it was undoubtedly progressive in its nature.

Dr. J. Porter Parkinson related the further history of a case of unusually Great Dilatation of the Heart. The patient had been shown to the society in January, 1901,[2] when the physical signs showed the heart to extend almost completely across the chest. There was a systolic and presystolic murmur both at the apex and in the region of the right nipple. There were remarkably few symptoms, dropsy only appearing during the last few weeks of life. He died in December, 1902. At the necropsy the heart was seen to be immensely enlarged and the pericardium was universally adherent. All the chambers were enlarged but especially the auricles and the right ventricle. The mitral orifice was exceedingly stenosed; the tricuspid valve was thickened and the orifice was somewhat stenosed. The heart weighed 30 ounces when empty of blood. The specimen was shown with the object of demonstrating that the systolic pulsation in the region of the right nipple was produced by the right auricle and not by the left auricle which, though much enlarged, lay at a distance from the surface.—Dr. Ewart remarked on the interest of the case as bearing on the causation of pulsation over the right auricular area.—Dr. C. W. Chapman referred to a somewhat similar case in which practically no symptoms existed.—Dr. Parkinson, in replying to Dr. W. Pasteur, stated that the pulsation over the auricular area was synchronous with the apex beat.

The annual meeting of the society was then held. The report of the council and the treasurer's statement of accounts were duly submitted and the usual votes of thanks to the retiring officers and council were proposed and adopted with acclamation. The scrutineers' report showed that the following gentlemen had been elected for the session 1903-04.—President: Dr. Frederick Taylor. Vice-presidents: Dr. D. B. Lees, Dr. H. A. Lediard, Sir William R. Gowers, Mr. H. H. Clutton, Mr. Henry Morris, and Mr. C. H. Golding-Bird. Treasurer: Mr. G. H. Makins. Council: Mr. J. Kingston Barton, Dr. F. E. Batten, Dr. J. Mitchell Bruce, Dr. J. Walter Carr, Dr. W. S. Colman, Dr. Lee Dickinson, Dr. S. H. Habershon, Dr. F. H. Hawkins, Dr. Kidd, Dr. Hector Mackenzie, Mr. F. W. Strugnell, Mr. Herbert W. Allingham, Mr. Leonard A. Bidwell, Mr. Walter Edmunds, Mr. J. Hutchinson, Jun., Mr. T. H. Kellock, Mr. H. Betham Robinson, Mr. Charters J. Symonds, Dr. C. S. Wallace, and Mr. F. C. Wallis. Honorary secretaries: Mr. Anthony A. Bowlby and Dr. W. Pasteur.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on May 15th, Dr. Frederick Taylor being in the chair.—Dr. J. Porter Parkinson showed a specimen of Colloid Cancer of the Peritoneum removed from a girl, aged 12 years. During life the abdomen was distended with free fluid and she was thought to be suffering from tuberculous peritonitis. On removal of the fluid large cells filled with colloid deposit were found in the detritus. An irregular hard swelling was then palpable in the hepatic area and some scattered nodules could be felt elsewhere. An abdominal section was subsequently made and the peritoneum was found to be sown with small masses of growth of a sodden semi-transparent appearance which microscopically were colloid cancer. Subsequently the abdomen became completely filled with irregular masses of growth which surrounded all the contained organs. The primary seat of the growth was thought to have been in the rectum.—Dr. A. E. Sansom thought that by reason of the patient's early age the case was probably a record one.—Dr. A. A. H. Partridge showed a boy, aged ten and a half years, the subject of Interstitial Keratitis who simultaneously developed an affection of the hands. He said that the cause to which the joint changes were due was an interesting question. The joints looked like those of osteo-arthritis but he supposed that they must be considered due to the general condition. An interesting point about the case was that the left hand became affected after the left eye and the right later—this happened in November, 1901; the right eye failed in January, 1903.—Dr. Edmund Cautley said that the disease did not seem to him to be a syphilitic affection of the joints; he was much more inclined to consider it a case of osteo-arthritis arising in a child the subject of inherited syphilis.—Dr. G. A. Sutherland said that he thought that the joint changes were probably syphilitic in origin.—Dr. George Carpenter agreed as to the striking resemblance between the child's condition and osteo-arthritis. He thought that there was periosteal thickening of the heads of the metacarpal bones and that the condition of the knuckles could not be distinguished from syphilitic epiphysitis.—Dr. F. Parkes Weber said that he had examined the case very carefully and the evidence was very strong in favour of the state of the joints being due to congenital syphilis. Unlike osteo-arthritis there was a complete absence of tenderness and the movement in the joints was almost perfect. The changes were almost entirely confined to the bones and the periosteum. Certainly there was just the slightest effusion into one or two of the joints. He regarded the case as one of phalangitis of syphilitic origin.—Dr. Cautley showed the Stomach and Œsophagus of an infant, aged 18 months, who had died from Diphtheria. The child was admitted into hospital for constipation and anuria and ten days later developed bacilluria, the variety being the bacillus coli. Subsequently the patient became feverish, profoundly asthenic, and died in 12 days from the onset of the fever. The œsophagus contained membrane in the upper third. One third of the mucous membrane of the stomach towards the pyloric end was covered with yellowish-grey membrane. —Dr. Watson said that he had obtained a pure culture of the Klebs-Löffler bacillus from the mucous membrane of the stomach and also in sections of the stomach wall.—Dr. Parkinson showed a case of Enlarged Bronchial Glands in a child, aged four and a half years, which was associated with a paroxysmal cough like whooping-cough. The associated signs were those of bronchitis with breath sounds weaker on the right side and in places somewhat bronchial in quality. There was much sputum which was free from tubercle bacilli. The fingers and toes were clubbed. He thought that there were enlarged mediastinal glands pressing on the right bronchus with secondary dilatation of the tubes and that the "whoop" was occasioned by irritation of the vagus nerve. The very continuous whoop was so distinct that the child was not allowed by the mother's friends to associate with their children and had been sent out of hospital on several occasions as a case of whooping cough.—Dr. Taylor showed a case of Athetosis in a girl suffering from mitral disease. She was suddenly attacked with right-sided hemiplegia during sleep and some twitchings of the right arm and leg were noticed at the onset. Involuntary movements commenced in the right hand and foot two days after the hemiplegia began. The condition was probably embolic and permanent.—Dr. Sansom said that there was no question as to the embolic plugging of the left middle cerebral artery. Plugging in a purely rheumatic case of heart disease was not quite so common as was sometimes thought.—Dr. Sutherland said that the case seemed to be one of chorea from the nature of the movements. The movements were very rapid for athetosis and there was also the fact of the rapidity of their onset, and there was the association of endocarditis which was a strong point in favour of chorea and he did not think that the absence of facial movements absolutely excluded chorea.—Dr. Taylor also showed a case of Acute Anterior Poliomyelitis involving the abdominal muscles as well as the legs and lumbar muscles. He said that the more he saw of cases of infantile paralysis the more he found that the abdominal muscles were involved and he thought that the lesions were as much primary there as in the limbs.—Dr. E. C. Williams (Bristol) read a paper on a case of Infantilism in a child, aged ten years, who had not grown since four years old. Her weight was 26 pounds and her height was three feet. She was awkward to manage and rather dirty in her habits. She could read her letters and count and answer simple questions fairly intelligently. There was no heart disease; she was free from congenital syphilis and rickets and she lost weight under thyroid treatment.—Dr. Carpenter drew attention to the association of infantilism in congenital syphilis with atrophied testicles. He suggested that Dr. Williams should make a rectal and bimanual exploration of the pelvic viscera and report upon the condition of the uterus and the Fallopian tubes and ovaries, as it would make the case more complete if that were done.—Dr. John McCaw (Belfast) read a paper on a case of Splenic Leukæmia in a child, aged 18 months. There was no history of syphilis and the patient was not rickety. The accessible lymphatic glands were enlarged. The spleen reached to the umbilicus and the liver also. The urine was loaded with oxalates and contained a trace of albumin. There was intense leucocytosis; the lymphocytes reached 99·2 per cent. of the leucocyte count. The red corpuscles were diminished by more than half and a few nucleated corpuscles were seen. The hæmoglobin was 39 per cent. She subsequently developed purpura and died soon afterwards. The spleen diminished in size very considerably before death and was not nearly so hard as it was previously to the touch. The swelling of the lymphatic glands disappeared to a large extent and they were not so hard.

---

ILFORD MEDICAL SOCIETY.—A meeting of this society was held on May 7th.—Mr. C. W. Mansell Moullin read a paper on the Treatment of Fractures into Joints and Sprains at the present day compared with that which was in vogue a few years ago. Formerly a Pott's fracture was put up in splints or in plaster-of-Paris for four or five weeks without being moved or touched in any way and as a result when the limb was taken down and the patient was assured that the fracture had united the limb was quite useless. It was cold, heavy, and stiff, all the muscles were wasted, the tendons were glued down to their sheaths, the joint could not be moved, and if the limb were used at all or allowed to hang down it became swollen and painful at once. It often took longer for the patient to recover from the effects of the treatment than it did for the fractured bones to unite. In Colles's fracture the results were even worse. Not only the wrist but the fingers were left stiff and painful so that the hand was helpless and useless. The knee, if the patella were broken, was more fortunate, for owing to the wide gap left between the fragments stiffness was not so common unless, as occasionally happened, the upper fragment became glued to the lower end of the femur by adhesions. In sprains, when, for instance, the internal semilunar cartilage became displaced or torn, the effect was just the same. The knee became cold and stiff as a result of the treatment. It had to be massaged and douched for weeks before it regained anything like its full range of movement and sometimes it never did so, especially in a hysterical girl. Rest was undoubtedly necessary for broken bones or torn ligaments to unite, but absolute rest, combined with uniform pressure, uninterrupted for weeks together, was thoroughly bad for every other structure in the limb—thoroughly bad even when there had been no injury, and worse still when there was a large amount of extravasated blood and effused lymph filling up all the interstices and matting everything together. In the treatment of a fracture leading into a joint the object was to replace the fragments in their natural relation and to keep them there until they were joined. But the extravasation of blood and the effusion of lymph must be checked as soon as possible. All that had been poured out already must be absorbed and driven into the lymphatics as soon as it could be. The muscles must be prevented from wasting. The joints must not be allowed to become stiff and the nutrition, the blood-supply, of every structure and tissue in the limb must have as much attention paid to it as the union of the broken bone. This could only be accomplished by systematic massage, begun very quietly and gently the day after the accident and continued every day, doing a little more each time until the swelling had entirely gone and the joint could be moved by the manipulation through almost its full range. There were some cases in which the injury was too grave or the patient was too violent, but these were very few; and even in them the line of treatment must be the same although it could not be carried so far. The limb must be placed upon a splint so contrived that it could be exposed thoroughly by removing a bandage without risk of displacement. In a Pott's fracture this could be readily done by means of a back splint with a moveable foot-piece. In a Colles's fracture a Carr's or a Griffith's splint answered in the vast majority of cases provided that the fragments had once been got into good position, but in many only a guttapercha wristlet was required. A fracture of the patella, on the other hand, required wiring. Mr. Mansell Moullin stated that for many years past he had wired every case of fractured patella and had never had a moment's uneasiness about them. No splint at all was necessary. The knee was bandaged after wiring and the patient was placed in bed and encouraged to move it about. At the end of eight or nine weeks patients treated in this way were able to walk, to run, to kneel, or even to kick with the injured leg. The massage might be carried out by an experienced nurse but as a rule, at first at any rate, the surgeon should do it himself.

BRITISH GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on May 14th, Dr. Heywood Smith, the President, being in the chair.—Dr. H. Macnaughton-Jones, using the epidiascope, showed Sections of Ovaries removed from patients who had for years been sufferers from incurable dysmenorrhœa. The sections (prepared by Mr. G L. Eastes) showed a condition of cirrhosis and cystic degeneration throughout the entire substance of the ovary, the capsule being considerably thickened and the cellular elements being almost indistinguishable in parts.—Dr. Macnaughton-Jones also showed a Uterus with the Adnexa removed by Professor Bumm's method. A carcinomatous mass occupied the fundus but the cervix was quite free from disease. The advantage of the operation (which Dr. Macnaughton-Jones had already described in the Journal of the society bearing date February, 1902) consisted in the rapidity with which it could be performed and its absolutely bloodless nature. Also there was no danger of wounding the ureters and the vault of the vagina could be dealt with according to circumstances. The operation was suitable to such a case as the present or comparatively small myomata or certain forms of malignant endometritis or deciduoma.—Mr. Charles Ryall confirmed Dr. Macnaughton-Jones's statements as to the bloodlessness and rapidity of the operation.—Mr. F. Bowreman Jessett, Dr. William Duncan, Dr. Mansell Moullin, and the President, while expressing their interest in Professor Bumm's method, concurred in the opinion that the uterus could be removed as quickly and with as little loss of blood by ligaturing the broad ligaments without forceps and they thought that the presence of such a number of the latter must be a disadvantage.—Dr. Bedford Fenwick showed two Enlarged Ovaries which had been adherent to a fibromatous uterus extending nearly to the ensiform cartilage and had therefore been removed with it. In a large number of hysterectomies he had found more or less gross disease of nearly every ovary and tube and if that were the case generally he thought it would be a grave error not to remove the ovaries with a diseased uterus.—Dr. Herbert Snow said that pain, though mainly due to tension of the capsule, might also arise from peritonitis or pressure.—Mr. Jessett, Dr. C. H. F. Routh, Dr. F. A. Purcell, and Dr. Duncan, while agreeing that the amount of disease shown in the sections quite justified the removal of the ovaries, spoke strongly in favour of conservative measures and of the importance of preserving a portion of even one ovary.—Mr. Jessett opened the discussion of his paper on Intestinal Obstruction, a rare complication of Ectopic Gestation, which was read at the last meeting. He said that owing to the pain being entirely above the umbilicus the case had been diagnosed as one of diaphragmatic pleuritis. The patient when he saw her had all the symptoms of intestinal obstruction. She had not been pregnant for nine years and her menstruation had been regular until, five days previously, she was suddenly seized with pain between the umbilicus and ensiform cartilage and became collapsed. An operation was performed but death ensued the same night.—Dr. Mansell Moullin said that he had met with two somewhat similar cases.—The meeting concluded with some further demonstrations from the epidiascope.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The eighth meeting of the session was held in the Medical Library, University College, Bristol, on May 20th, Mr. G. Munro Smith being in the chair.—Mr. John Chiene, professor of surgery, University of Edinburgh, gave an address on Movement, laying special stress on the importance of voluntary movements in the treatment of fractures and sprains.

Reviews and Notices of Books.

Therapeutics of Infancy and Childhood. By A. JACOBI, M.D., LL.D. Third edition. London and Philadelphia: J. B. Lippincott Company. 1903. Pp. 560. Price 18s. net.

IT is probable that the first edition of Dr. Jacobi's "Therapeutics," which was published in 1895, was not extensively read in this country except by those who make a special study of the diseases of children. Times change, however, and the industry of American authors and publishers has introduced so many excellent medical text books to the notice of our own students that it has become a fashion among us to rely on American publications for much of the information which is necessary for our professional education. In no department of medicine is this confidence in American books better justified than in those which are concerned with the diseases of children. Dr. Jacobi may fairly be regarded as the father of pediatrics, and although he is better known to fame as a clinician than as a writer, owing to the respect with which everything which he has to say on the subject of treatment is received in this country, it may safely be assumed that the present edition of his "Therapeutics" will be far more widely read than was the case with the former editions. The volume under review is a systematic and complete treatise on the therapeutics of childhood and it is by no means confined to medical subjects but includes the treatment of a number of conditions which more usually come within the province of the surgeon. For instance, anatomical deformities, congenital luxations, fractures of bones, hernias, and hydrocele all receive the attention of the author. Although the various conditions are seldom illustrated by cases, nevertheless, without this popular method of making a work on therapeutics interesting, the author contrives to hold the reader's attention by the vigour and directness of his style.

Dr. Jacobi, as is well known, is no great believer in drug treatment and much of his advice depends on the application of prophylactic measures and dietetic and hygienic management. He appears, however, to have faith in the administration of arsenic and phosphorus in the treatment of cases which depend on constitutional dyscrasias and neurasthenic states. Dr. Jacobi, in common with many other experienced clinicians, has certain prejudices in treatment. For instance, his confidence in decoctions of cereals and dextrinised flours in the routine feeding of infants appears to us to be put on a higher pedestal than it genuinely deserves. We do not imagine that there are many authors who would contest with him his right of priority in the usage of these diluents, nor do we regard the question as of sufficient importance to make it a ground for dividing the medical world into two classes, the faithful and the unfaithful, those who believe in cereal decoctions and those who do not. The truth is that in experienced hands success in the feeding of infants can be achieved either with or without the assistance of any diluents other than water. Another matter with which we have greater sympathy is the free administration of water to infants and children as a routine practice. This is a humane and scientific precaution which is too often neglected. Another point which Dr. Jacobi urges is the superiority of cane sugar as opposed to milk sugar and he adduces arguments in favour of the former which we do not consider to be convincing. On the subject of cream the author's views do not agree with those which are generally held. He minimises the troubles of nutrition which may arise from a deficiency of this element and we cannot help thinking that he exaggerates the dangers which are likely to accrue from excess. For instance, he apparently regards the production of rickets as almost independent of starvation as regards fat. He considers over-alimentation as at least as dangerous as under-alimentation in the production of this nutritional disorder and in this latter contention we are disposed to agree with him, although this view is not generally held.

In discussing the question of difficult dentition we notice the statement that "dentition is a physiological process" and that "the long period of dentition is also the time of many disorders and diseases which are not easily diagnosticated and may tempt the practitioner to suggest or accept a diagnosis of difficult teething," and farther he says, with an undercurrent of sarcasm, that "there are, fortunately, practitioners who prefer making a diagnosis of the real condition of the ailing baby, and that and its improvement or cure comprise *the main treatment I recommend for difficult dentition.*" The aphorism that dentition is a physiological process is a meaningless truism which has crept into one text-book after another until practitioners almost hesitate to ascribe any of the conditions which they meet with during the period of dentition to causes which directly follow from this "physiological act," lest they expose themselves to the ironical gibes of superior persons. Of course, nobody doubts that the act of cutting milk teeth is just as much a physiological process as that of cutting the wisdom teeth, or, for the matter of that, of the act of parturition, but all the same the three processes are, unfortunately, apt to cause a disturbance in certain subjects of the general bodily equilibrium which is, to say the least, exceedingly disagreeable to the victims. It is true that bronchial, gastric, or intestinal symptoms frequently arise during the period of dentition in infants who have been mismanaged and that these symptoms might never have arisen had no such mismanagement been in force, but the general disturbance of the nervous system which occurs from the peripheral irritation of the erupting tooth must legitimately be regarded as the exciting cause of the special morbid manifestations in the weak or mismanaged organ.

There are several minor points which a careful reading of this book may suggest for criticism. We notice on p. 5 that it is stated that "in face of the fact that the percentage of fat in cow's milk and in human milk is practically the same, the addition of cow's cream to cow's milk to make it more similar to woman's milk does not appear very rational." The *rationale* of the procedure would be more evident if the author had used the expression "diluted cow's milk" instead of "cow's milk." We imagine that cream is never added by reasonable persons to undiluted cow's milk for the purpose of infant feeding or for the purpose of bringing it up to the standard of human milk. On p. 132 there is the following sentence: "Laryngismus stridulus, the crowing inspiration of infants, is almost always connected with craniotabes and caused by its meningeal and encephalic results." And on the following page it is stated that "the arteries in rhachitis are abnormally large and that the great width of these vessels lowers the blood pressure. That is why the muscles and bones suffer from insufficient nutrition and why the circulation in the respiratory organs is slow and sluggish, with a tendency to produce congestion and catarrh." These pathological explanations are not, to our thinking, convincing or logical.

In his preface Dr. Jacobi acknowledges that he has freely availed himself in the revising of his book of the criticisms of reviewers. We may therefore be pardoned if we add one more criticism and call attention to the word *nucleon* which appears in several pages and also in the index and which presumably is not a *lapsus calami* or a printer's error; *nuclein* is, we imagine, the word which Dr. Jacobi intends to use. In conclusion, we may say that the main principles of treatment which he recognises and describes are quite beyond criticism and we strongly recommend all those who take a practical interest in the treatment of infants and children to add this volume to their libraries and to refer to it whenever they find themselves in a difficulty or come to the end of their own therapeutic resources.

Atlas und Grundriss der Allgemeinen Diagnostik und Therapie der Nervenkrankheiten. (Handbook of the General Diagnosis and Treatment of Diseases of the Nervous System.) By Dr. W. SEIFFER, Lecturer to the University and Senior Surgeon to the Hospital of Royal Charity for Nervous Diseases. With 24 Plates and 264 Illustrations. München: J. F. Lehmann. 1902. Pp 380. Price 12*s.*

THIS is the twenty-ninth volume of Lehmann's series of medical handbooks, which has already won a considerable reputation on account of the excellence of the plates and drawings by which the subjects of the series are illustrated. In the present volume this feature is well maintained. The text is admirably illustrated with reproductions from photographs of patients suffering from the diseases under consideration and the coloured plates are especially worthy of the highest praise. The text is quite satisfactory so far as it goes but it cannot be said to give more than a very elementary outline of the subject. The greater part of the book is devoted to the symptomatology and diagnosis of nervous diseases. The author deals with his subject by the inductive method. Facts to be observed—namely, the signs and symptoms of disease—are first considered and then the diseases which may give rise to them This part is therefore arranged according to the nature of the symptoms. Motor phenomena are taken first—conditions of paralysis, atrophy, incoördination, spasticity, and contracture; then follows an account of sensory disturbances; and finally reflex, vaso-motor, trophic, and visceral disturbances are brought under review. While this method possesses certain advantages from a practical point of view it fails to give a well-defined picture of a symptom-group representing a certain disease, and it is only by possessing some such mental picture that one nervous disease can be clearly differentiated from another. In a book specially devoted to the diagnosis of nervous diseases the reader would expect to find perhaps a fuller discussion of the lesser signs and symptoms as aids to difficult differential diagnosis, especially in regard to the localisation of cerebral and cerebellar tumours; but as the title indicates the subject is only treated in a very general manner and the book is to be regarded therefore rather as an adjunct to the ordinary text-book than as a complete manual on the subject. In the second part, which deals with the treatment of nervous diseases, the author enters into practical details of considerable value in the treatment by massage, electricity, baths, and exercises.

Les Injections Mercurielles Intramusculaires dans la Syphilis. (Intramuscular Injections of Mercury in Syphilis.) Par Dr. ALFRED LÉVY-BING, Ancien Externe des Hôpitaux, Ancien Interne de Saint-Lazare. Paris: C. Naud. 1903. Pp. 322. Prix 5 francs.

IN this interesting treatise Dr. Lévy-Bing gives a full account of his experiences in the treatment of syphilis by the intramuscular injection of mercury. In the space of two years he has carried out more than 6000 injections on about 500 patients. These injections were made with all the different mercurial preparations now on the market for the purpose and he is therefore in a position to draw definite conclusions as to their relative merits and demerits. The first few chapters are devoted to a consideration of the advantages and disadvantages of this form of treatment, the indications and contra-indications for their use, and the technique of the injections. The author claims for this method of treatment that the quantity of mercury received into the system is known exactly and that it can be accurately controlled, that it brings the patient more rapidly and surely under the influence of the drug, and that it does not cause the same gastro-intestinal disturbances as when it is exhibited by the mouth. Its chief drawbacks are: (1) the pain accompanying the injection and (2) the local disturbances—inflammations, indurations, and abscesses—which may arise at the sites of injection. The rest of the book is taken up with a description of the author's experiences with each mercurial preparation. In every case he gives the pharmaceutical details of the preparation, together with the dose for injection, and exemplifies its action by cases. The chief indications for which he recommends the adoption or rejection of a preparation are: (1) the pain caused by the injection; (2) its liability to set up local trouble; (3) its tendency to cause mercurial symptoms; and (4) its medicinal efficacy. The preparations are divided into soluble and insoluble. The soluble act more rapidly and are less painful but have the disadvantage of requiring daily repetition, whereas the insoluble preparations need only to be injected about once a week. Of the soluble preparations Dr. Lévy-Bing considers the biniodide of mercury in aqueous solution to be by far the best both on account of its efficacy and also its innocuousness. The perchloride is more painful and frequently gives rise to stomatitis and diarrhœa. Among the insoluble compounds the so-called "huile grise" is recommended, consisting of a mixture of mercury, lanoline, and vaseline. Calomel is by far the most rapid and efficacious in its action, but its injection is very painful and frequently gives rise to local inflammation and even abscess. Most of the other preparations are condemned either on account of the pain and local trouble to which they give rise or on account of their medicinal inertness.

The treatise is a valuable contribution to an important branch of therapeutics and is a thoroughly scientific record of the author's experiences.

Variations in Animals and Plants. By H. M. VERNON, M.A., M.D. Oxon., Fellow of Magdalen College, Oxford. London: Kegan Paul, Trench, Trübner, and Co. 1903. 8vo, pp. 418. Price 5*s.*

DR. VERNON in his preface to this contribution to our knowledge of the subject of variation apologises for making a large use of instances collected by himself from his own original investigations into the subject. This apology we consider to be quite unnecessary and, indeed, the very fact that the author has relied largely upon his own views and discoveries not only adds to the interest of the book but raises it at once above the level of the mere manual. It is an example—which might with advantage be more universally followed—of precisely the right method of book-producing.

At the present moment the facts of, and theories concerning, variation occupy a very prominent position in the biological world. Many workers in this country and abroad are concerned exclusively with these important problems of which the solution, if indeed it be possible at present, will provide the key to the explanation of evolution. The novice in these matters who would be abreast of current discovery and speculation is led by degrees from ascertained facts to its interpretation and in a very clear fashion is introduced to the methods now in vogue of representing in a graphic way the facts of variation. The more severely mathematical methods of stating these facts are not put forward by Dr. Vernon. There is thus nothing to prevent the person of average intelligence from profiting much by a perusal of this plain statement of variation in animals and plants. Naturally, as the author is himself a zoologist, the facts of animal variation preponderate over those of plant variation. Dr. Vernon is committed to no particular theories; he reviews and discusses the facts in a perfectly fair manner, and without any of that acrimony which this particular study seems to have produced in its votaries. Such ferocity of controversy is, we fear, rather a hint that the matters debated are, after all, not nearly ripe for solution, if, indeed, they ever will be; for it is invariably subjects quite or almost unknowable which breed rancour in disputants. The believer in every cause of variation will find some facts to support his views in this volume. The direct effects of external agencies, such as light and food, are amply stated and the author by no means thinks that natural selection is the "universal key," as is apt to be held by the more extreme followers of Darwin and Weismann. Some highly important experiments made 40 years ago by Mr. Gregson upon the effects of change of food upon the adult moths hatched from the caterpillars thus experimented with are appreciatively quoted by Dr. Vernon; and a very remarkable case of a similar nature recorded by the late well-known entomologist Mr. Newman is cited as an instance of the direct effects of food. This naturalist fed the "large tortoiseshell" butterfly caterpillars upon nettles and discovered that the resulting butterflies had many of the characters of the "small tortoiseshell," a species which normally feeds upon that plant. There can, in fact, be no doubt whatever that direct influences of the environment play an important part in the production of new varieties, and that therefore they must have played such a part in the past. More important, of course, from the point of view of the origin of species is the fact recently stated by Dr. Standfuss that an artificially produced variation "bred true" and produced its like.... It is plain, therefore, that that entomologist has produced an actually new form of life.' But though it may be shown, and in our opinion has been shown, that variation can be produced by varying salinity of water, by varying temperature, and by other such causes the action of natural selection is not necessarily thereby eliminated. On the contrary, it is easy to see on theoretical grounds where it could "come in" in many of these cases. The real difficulty for the believer in natural selection as the sole cause of survival is to connect its eliminating action with minute variations which seem to have, as it were, no utility. It is intelligible, for instance, that the minutest increase of lung tissue or of the thickness of the ventricles in a running animal might just make the difference between its capture by a carnivorous pursuer or its escape, but it is not so clear why the minute differences of microscopic sculpturing upon the bristles of annelids should occur. In this direction lie the labour and toil for those who would ascend from the pit of ignorance.

Atlas und Grundriss der Topographischen und Angewandten Anatomie. Von Dr. med. OSKAR SCHULTZE, a.o. Professor der Anatomie in Würzburg. Mit 70 Farbigen Tafeln nach Originalen von Maler A. SCHMITSON und Maler K. HAJEK, sowie 23 Textabbildungen. München: J. F. Lehmann. 1903. M. 16. (*An Atlas and Epitome of Topographical and Applied Anatomy.* By Dr. OSCAR [illegible] Coloured Plates after [illegible] HAJEK, and 23 Illus- [illegible] F. Lehmann. 1903. Pp. 156. Price 16 marks.)

DR OSKAR SCHULTZE adopts as his motto the words, "think anatomically if you would be a physician." This atlas and epitome of topographical and applied anatomy of which he is the author will certainly engender this method of thinking in those who read it. The volume has the advantage of being of handy size (about 8 by 10 inches), which is double that of the series of hand atlases which we already owe to German enterprise. This increase in size is a decided gain, allowing a far better display of the plates. The work is beautifully illustrated and the descriptive letterpress is concise but at the same time more than a bare enumeration of unconnected but important anatomical facts. The book is arranged in sections, each of which is devoted to a different region of the body, the head, neck, upper extremity, thorax, abdomen, pelvis, and lower extremity being treated in the order mentioned. At the end of every section is printed a series of examination questions calculated to bring into prominence important points and to afford a ready test of the information acquired by the reader. The whole work is essentially practical and the illustrations have been chosen with considerable discrimination. All the coloured plates are good and the majority of them are of a very high order of excellence. Half a dozen of the plates are representations of His models with which most, if not all, English students are familiar. Many of the others are drawn from formalin preparations. The lithographic plate No 10 and the coloured plate No. 54 showing the relations of the thoracic aorta are very instructive, as also is Fig. 54 which brings out in a striking differences of opinion. From a careful review of them we unhesitatingly state that in our opinion the curriculum is a great improvement on that at present in force and that students who follow it will be better medical practitioners than would have been the case had they studied under the former scheme. We agree with the statement made by Dr. BRADFORD in convocation that under the new regulations the schools will be further encouraged to develop higher education and research in many departments, especially in physiology and pathology. We would urge those who are disposed to take exception to special details to remember how very complicated a question medical education has become and how impossible it is to please all parties. It cannot be decided how some of the changes will work out till they have been put in practice. The ease with which teachers are now able through the Faculty of Medicine to draw the Senate's attention to defects in the curriculum and to submit proposals for its improvement should insure the speedy discovery and correction of any points that have been overlooked in drafting the new regulations.

Another subject of interest at present under the consideration of the University is the question of instituting special degrees in dentistry to which we called attention in our last issue. The statutory commissioners established a board of studies in dentistry and this board having been duly constituted recently presented to the Senate a report upon the question of degrees. This report, together with a minority report, was last week submitted to a meeting of the Faculty of Medicine. As will be seen from a notice of this meeting in another column the faculty expressed an opinion adverse to the proposal to establish special degrees. As both the majority and minority reports recommended that degrees should be instituted it would appear at first sight that the faculty had shown a want of sympathy with the desire of the dental profession. As the result, however, of some unexplained cross-voting by members of the board of studies upon a somewhat irrelevant amendment the issue presented to the faculty was confused. As we stated last week the question is an important and difficult one and we trust that the proposal will not be abandoned without further careful consideration. Upon those interested in this question, as well as upon those interested in the general development of the University, we would urge the importance of united action and efficient organisation.

◆

The Infected Blankets.

WHETHER or not the outbreak of enteric fever which occurred on board the reformatory ship *Cornwall* is to be attributed to the infected blankets which were discovered on the vessel is a matter concerning which an open mind must be preserved until the matter has been investigated in a systematic fashion and a report thereon issued. If the necessary detailed investigation has not yet been commenced it is to be hoped that the Local Government Board or the Home Office will undertake it. But whatever may be the facts as to the causation of the outbreak there can be no two opinions as to the necessity for fixing the blame upon those responsible, either in a positive or negative sense, for the dissemination over this country and, for anything we know to the contrary, other countries of soiled and, at least in some instances, specifically soiled blankets. Whether blankets alone have been thus scattered, or whether, in addition, other disused and possibly infected material has found its way into public use cannot be yet stated, but we trust that inquiries in this direction will be made by the authorities concerned.

That there are certain regulations which are intended to prevent the sale of infected bedding is but small comfort to the public in the circumstances, since it is clear that the regulations are in point of fact not sufficient to prevent such materials from falling into the hands of the public. It would, of course, be unreasonable to assume that the whole of the blankets which it is alleged were sold at the Cape for $2\frac{1}{2}$*d.* apiece were blankets which had been used in hospital by patients suffering from recognised enteric fever. It may, indeed, be subsequently found that at least some of the blankets which have been demonstrated bacteriologically to contain the living enteric fever bacillus may have been used by soldiers who were in the early and unrecognised stage of the disease and who had passed on to other places, leaving behind them the blankets which they may have specifically soiled. But however this may be, the fact that in practice blankets, an uncertain number of which are infected, have found their way into the public market remains, and the public health service of this country has a right to ask not only that the matter shall be probed to the bottom but that satisfactory assurances shall be given that a recurrence of such a risk, on however small a scale, has been provided against. It cannot, we think, be said that the answers given in the House of Commons to questions directed to the elucidation of the mystery have evinced a sufficiently serious appreciation on the part of the War Office of the material risk which has been run by the public, and although there is obviously no need for alarmist statements we trust that the lay public health service will urge upon the Local Government Board the necessity for pressing the thorough investigation of the subject. If our port sanitary authorities throughout the country are to have placed upon them the duty of disinfecting all the bedding, clothing, and the like, which reach our shores during months or years after the cessation of the numerous campaigns in which this country is at intervals engaged, the claim for a national subvention which the port sanitary authorities have made from time to time will be very difficult to resist. It would seem clear, however, from the recent occurrences that no disused bedding, whether it has served for hospital purposes or not, should be placed upon the markets until it has been cleansed and *efficiently* disinfected. The seizures of blankets which have now taken place in numerous parts of this country will possibly lead to unfortunate action on the part of the owners of such goods, and this is more likely to be the case in places where the absence of proper plant for cleansing and efficient disinfection has resulted in the destruction of the blankets. Every local authority ought morally, if not legally, to possess plant wherewith both these processes can be performed. The necessity for the previous washing of the blankets in cold water arises, apart from general

princip
disinfection by steam, which, as is well known, is the only method by which efficient disinfection can be performed, is apt to fix permanently any pre-existing stains. But we would urge upon local authorities the importance of incurring no risk as to the public health and if the infected articles cannot be adequately disinfected we trust that no parsimony will prevent the destruction of the articles in question and the payment of a fair compensation to the owners.

In some ways this regrettable occurrence will expose us to the ridicule of certain other nations, but nevertheless in no other country in the world does there exist a public health service which could have acted with greater promptitude and efficiency than has been the case in this country. The action of our port and inland sanitary authorities and of the central health department has been such that the country may well feel proud of its sanitary administration. From a purely scientific standpoint the occurrence is not without importance as it raises interesting points as to the persistance of vitality on the part of the enteric fever bacillus when this organism is retained in circumstances unlikely to promote its destruction. Much useful work in this direction has already been done by Dr. SIDNEY MARTIN and Dr. A. C. HOUSTON for the Local Government Board, and Major R. H. FIRTH and Major W. H. HORROCKS have also made valuable contributions to the subject. In this connexion we are glad that the desirability of a joint inquiry into this subject by the War Office and the Medical Department of the Local Government Board has been pressed upon the authorities.

◆

The Collection and Distribution of Milk.

DIVERGENT opinions are held by bacteriologists and by medical practitioners whose work lies chiefly among children as to the advisability of sterilising the milk which is given to infants. It is maintained by many that the process of sterilisation causes a degree of depreciation in the food value of milk which is not compensated for by the diminished risk of infection through the agency of the micro organisms which milk is apt to contain and for the development of which it forms such a suitable medium. On certain points, however, there is general agreement. The importance, for instance, of subjecting milk to as few chances as possible of becoming contaminated is not likely to be disputed and to achieve this the collection and the distribution of the fluid must be conducted with the strictest sanitary precautions. Again, in order that the milk of cows shall realise for human beings that ideal of the "perfect food" which elementary text-books of physiology credit it with approaching, it must undergo certain modifications and these may take one of two directions—the production, on the one hand, of a nutritive agent approximating in composition as closely as may be to normal human milk or, on the other, of a substance which is neither cow milk nor "humanised" milk, but which is specially adapted to meet some particular abnormal digestive condition. In regard to all these matters much has been done in this country. Sanitary authorities acting through their medical degree of control over the supply of milk to the districts within their jurisdiction, while private enterprise on the part of the larger dairies has made provision to satisfy the demand for preparations made from milk. At Battersea and at St. Helens in Lancashire the respective borough and county councils have entered the field as purveyors of milk of guaranteed purity. Although their undertakings can hardly be said to have passed beyond the experimental stage we have evidence of a public spirit which is worthy of commendation. Something is also done by health officers in the way of circulating leaflets bearing upon the relation of the consumption of milk to infectious disease and recently it has been suggested that systematic instruction as to the possibilities, for good and evil, of milk should be imparted in board schools, at least to the elder girls.

But there is still room for improved methods of disseminating knowledge and it would seem that here, as in so many other instances, we have something to learn from our continental friends. From May 2nd to 10th there was held in Hamburg an Exhibition for Promoting the Hygienic Supply of Milk which, since it affords many useful hints as to further progress, may be considered in some detail. The exhibition was divided into sections dealing with the milk question in many of its aspects. Thus in Section A, which was devoted to "milk production," were shown cows of well-known breeds which were made the subject of important demonstrations in the art of milking and the general management of shippons. The best styles of stall fittings and of utensils for the collection of milk were displayed, while the matter of suitable clothing for the milkers received attention. In Section B, which dealt with the veterinary control of the cows and of the milk-supply, information was supplied in regard to legislation relating to the control of cowsheds. The measures to be taken in case of an outbreak of disease among cows were set forth and an exposition was given of the forms of disease to which milch cows are liable, with special reference to diseases of the udder. Here, too, were included the effects of poisonous or otherwise unsuitable food-plants and of impure water. This branch of the subject was completed by reference to the materials used and the procedure adopted in disinfecting the stalls. Section C was concerned with the utensils and apparatus employed in the conveyance of milk by road or rail or water and in its distribution. It embraced the weighing and measuring of the fluid and the cleansing and filling of bottles used for its storage. The processes of separation, cooling, pasteurisation, sterilisation, and concentration were also dealt with in this section. The fitting up of establishments, small and large, for the sale of milk was the subject-matter of Section D. Section E had reference to the legislation concerning the sale of milk, the police supervision of dairies and milkshops, the taking of samples for analysis, and the chemical and bacteriological methods employed in such analysis. In the scientific Section, F, it was possible to learn something of the history and literature of the employment and distribution of milk and also of the means by which instruction in dealing with milk is provided. To Section G was allotted the display of preparations made from milk—e.g., preserved milk,

milk adapted to the requirements of infants, milk for therapeutical purposes, and milk foods of various kinds. Section H illustrated the arrangements and apparatus necessary for properly dealing with milk in private houses.

It ought to be possible to hold an exhibition of this kind in London. Whether to do so would be financially profitable to the promoters is, perhaps, doubtful, but the educational value of the proceeding would be so great as to justify contribution from the national purse. The idea, too, is one capable of development. Without obscuring the scientific aspects of the exhibition more popular elements might be added. The art and mystery of butter-making and sophistication might be expounded and demonstrations might be given of the manufacture of the many varieties of cheese. Experienced cooks might offer for inspection samples of the thousand-and-one dishes into the composition of which milk enters and a corner might be reserved for teaching something of the applications of koumiss. There is here, indeed, almost enough material for an Earl's Court exhibition, though it might be a little undignified to combine amusement with instruction, in the way beloved of the Londoner, by giving him an opportunity of shooting the chute on a milkman's-barrow or by converting the great wheel into a gigantic churn.

Annotations.

"Ne quid nimis."

THE TREATMENT OF YOUTHFUL CRIMINALS AT THE ELMIRA REFORMATORY.

A VALUABLE and interesting report for the year 1902 dealing with the treatment of young criminals at the New York State Reformatory at Elmira has just been published. The total number of inmates who have been in the institution during the year was 2134, of which number 858 have been cases admitted during the year. 611 inmates were discharged from the reformatory during the year. Nearly three years ago a careful examination of the whole inmate population was made by Dr. Frank W. Robertson, then senior physician, and a number of inmates were found whose mental condition was so abnormal or disordered or defective that they were totally unfitted to derive benefit from the special advantages offered by the institution. They were accordingly transferred to the Matteawan State Hospital for the Insane. Dr. Robertson, now the general superintendent of the reformatory, states in his report that "the reformation of the unfortunates committed to the institution has been vigorously prosecuted during the past year." A marked improvement in caring for the bodily and mental health of the inmates has resulted in a lower annual death-rate than in previous years and the improvement of general physique has rendered them more susceptible to reformative measures. Owing to the fact that the inmates come principally from the lowest strata of society they are below the average standard of physique and bodily health, while they are mentally and morally below the normal standard. Very often born of dissolute, pauperised parents such a child is brought up in squalor and dirt, among companions who are equally unfortunate, without a school education as a rule, and therefore without the constitution, training, or education with which to make a proper start in life on arriving at the age of adolescence. "At this age," adds Dr. Robertson, "he frequently runs away and becomes a tramp, or is obliged to leave home and shift for himself," and being thus largely left to his own devices and finding it difficult to obtain a living he soon violates the law and is sent to prison or to the reformatory. Such is the class of youths sent to the Elmira reformatory for the special education and training which are devised to reform them and to make them fit and capable of earning an honest living in the State. The teaching and training undergone include systematic drill, education in reading, writing, and arithmetic from kindergarten to higher grades, and technical and practical instruction in trades and handicrafts suitable to the individual capacity of each inmate. The number who have daily instruction in the "trades school" has varied from 1100 to 1250. Among the trades taught are photography and etching, applied electricity, mechanical engineering and fitting up steam and other machines, carpentry, bricklaying and building and pattern making. Printing and bookbinding are also taught, and the excellently printed and bound illustrated volume of the report before us shows that the grade of skill attained in this department is high. Moral and religious teaching of a non-sectarian character occupies an important place in the scheme of education. The health of the institution was very good during the year, the total number of deaths being seven. The annual death-rate in recent years has been, in fact, much less than the normal death-rate among the general population of the State. The aim of the reformatory is to receive under sentence from the law courts a certain class of convicted youthful criminals and to return them to the community as intelligent non-criminal young men prepared to take places in the mechanical trades above the lowest ranks of labour. It involves the education of the inmate in a trade, in letters, and in conduct and presupposes that he has the capacity for such education. About one-fifth of the inmates, however, are found to be mentally defective in such a degree as to be incapable of more than slight improvement. The majority of the inmates, however, prove successful in achieving a moderate, and some few even a high, degree of skill in a trade and after discharge from the institution take their place among competent workers and wage-earners in the State. The report is valuable and highly interesting and deals with one of the most important social problems of the day.

LUNACY AND ALCOHOLIC EXCESS: A GROWING SOCIAL EVIL IN SCOTLAND.

THE alarming growth of lunacy in Scotland and especially of those forms of it attributable to alcoholic excess has moved the municipal authorities of Glasgow to appoint a special committee to inquire into, and to present a report upon, this matter. A copy of this report, which is now before us, dated April 27th, 1903, furnishes serious matters for consideration. The committee records with concern the fact that of 565 admissions to the Glasgow district asylums at Woodilee and Gartloch and 213 admissions to the observation wards of the poorhouses during 12 months no fewer than 259, or 33 per cent., have been traceable to alcoholic intemperance. The inquiries made by the committee and by the medical superintendents of the asylums show that want and privation were not elements in the production of these cases of alcoholic insanity, for in the large majority of instances the home conditions and surroundings were good and the earnings in 19 typical cases were from 19*s.* to 60*s.* per week. "It is beyond question," adds the report, "that a large number of the insane sent to the asylums in previous years and still inmates thereof are cases of the same nature, so that the question calls for the earnest consideration of the Government and the public." The committee accordingly has forwarded copies of its report to the Secretary of State for Scotland, the General Board of Lunacy, the town council, and the press. The condition referred to in the report is unfortunately not an isolated or exceptional one, for a perusal of the reports of the Royal Edinburgh Asylum during the past few years bears out the same conclusion as regards alcoholic insanity in the capital of Scotland. The growth of lunacy in a ratio rather more rapid than that of the growth of the general population of the United Kingdom may now be regarded as a fact fairly well established, while it is also noteworthy that alcoholic insanity has been increasing on the whole somewhat rapidly during the past two or three decades in great cities and industrial centres. The whole problem, however, is a very complex one and so fraught with difficulties that much more light and knowledge are needed on the matter before any definite proposals, legislative or otherwise, can be recommended for dealing with this grave social evil.

THE LESSON OF THE GREAT MOTOR-CAR RACE FROM PARIS TO MADRID.

"IT'S the pace that kills" was surely never more painfully illustrated than in the series of disasters which took place in connexion with the great motor-car race from Paris to Madrid. The pleasure derived from driving a motor-car for many hours at a speed of anything over 60 miles an hour is one which is a little difficult to understand and which can only be realised with grave risk to the public at large. We need not enter into particulars but may record the fact that all possible types of accident occurred, resulting in four deaths of *chauffeurs*, serious injuries to six or seven participators in the race, and at least four deaths amongst the spectators. Motor-car racing is thus shown to be a danger alike to driver and to pedestrian. Much as the catastrophes must be deplored there can be but little doubt that they have carried a most striking lesson to the whole civilised world. High speeds cannot be tolerated on the highway so long as that highway is the common road for foot travellers and horse-drawn vehicles—and we are bound to add for animals of a more or less domesticated type, for who can be held responsible for the stray dog?—indeed, in the race referred to one of the motor-cars ran over a dog so that the car swerved and dashed into a tree, the *chauffeur* was killed, his companion badly injured, and the car smashed to pieces. As well might we expect it to be safe to allow a coach-and-four or a market cart to drive along the track of the London and North-Western Railway as far as Crewe. What control over a motor-car travelling at the rate of an average speed of 60 miles an hour can a driver be expected to possess when he suddenly encounters a big stone, a curve in the road, or something crossing his path at a cross road? In this country it would be mathematically impossible to take some of the curves of our high roads safely. The question is not what the motor driver is able to do with safety to himself but how far his operations should be controlled in the interest of the safety and comfort of the public. Drivers of motor-cars cannot be allowed to claim privileges which are not possessed by other users of the road. The interests of the public generally are the first consideration. The designers of the roads as originally made and maintained did not contemplate such a class of traffic as motor-cars and there are very few sections of English highways on which an average speed of 60 miles an hour could be permitted with safety. The English high-roads are seldom uniform in width, surface, or direction; indeed, it is constantly forgotten that after all England is a small island through which it is impossible to construct roads of the uniform straightness and width of the *via nazionale* of the Continent. We must not be taken to say that this fact is an absolute argument in favour of banishing motor-cars altogether from our highways, but we do urge that motor-car owners and drivers should possess their souls in patience until some sort of a compromise is effected which will adapt the roadway equally for all. The road must not be, can never be, a monopoly. We bear in mind the fact that in this country we have as far as possible kept the motor-racing instincts from having outlet on our highways; nevertheless, it must be admitted that in spite of this some ugly accidents have arisen. The motor bicycle already has been resorted to as a source of competitive struggle as regards speed on special tracks. In such a competition two persons lost their lives and several others were injured, the race being a comparatively short one, at Bristol last week. We are aware that something may be said against the placing of a legal limit upon the speed of motor cars, but it is necessary to bear in mind that those who can indulge in motor-car riding are an infinitesimal number compared with those who do not care, or else cannot afford, to do so, and the safety of the lives and the limbs of the public is the matter of first consideration. We venture, therefore, to think that the proposal to withdraw the speed limit is a dangerous one despite the fact that all responsibility is to be fixed upon the motor-car driver. Impending legislation should be directed, if possible, not to the extinction of the comparatively new, popular, and what will some day be a valuable, means of locomotion, but against its abuse, and we cannot resist the impression that a system of graduated speeds according to circumstances could be fixed which would place no undue restraint upon the motor-cars and which at the same time would afford reasonable protection to those who employ ordinary means of locomotion. Above all the mania for excessively high speeds must be discountenanced, at any rate, while high-roads are as they are, just as the "scorching" cyclist was very properly "scotched" a few years ago. Trials of speed are certain to bring discredit upon the motor industry which, presumably in its own interests, initiated them.

THE CYTODIAGNOSIS OF AFFECTIONS OF THE SPINAL CORD, WITH SPECIAL REFERENCE TO TABES DORSALIS.

MUCH attention has been given by neurologists during the past three years to the clinical study of the cerebro spinal fluid and the subject of the cytodiagnosis of affections of the spinal cord. A valuable account of the facts ascertained and the results achieved in these respects in cases of tabes dorsalis, general paralysis, and other nervous affections is published in the *Revue Neurologique* of March 30th, the chief contributors being Professor Brissaud, Professor Widal, Dr. Pierre Marie, Professor Babinski, and Dr. Gilbert Ballet. In the first of these communications Professor Widal, Dr. Sicard, and Dr. Ravaut stated that since Babinski and Nageotte had reported their collected observations on the cytodiagnosis of 26 cases of tabes in May, 1901, much work has been done on the subject. These two authors had stated that a more or less marked lymphocytosis was present in the cerebro-spinal fluid in 25 out of the 26 cases examined. Since then Professor Widal and his colleagues had examined the cerebro-spinal fluid in 37 cases of tabes dorsalis, both of recent origin and of long standing, drawn from the wards of Professor Raymond and others. Lymphocytosis was observed in all these cases except one. In 30 cases the lymphocytosis was distinctly confluent and in six it was discrete. In all these cases the lymphocytes were sufficiently numerous to enable at least from six to 10 to be counted in each field of the microscope according to the technique pursued by the authors. These lymphocytes were the most numerous cellular elements present in the cerebro-spinal fluid, but sometimes large cells, which were difficult to classify as mononuclears or as endothelial cells, were also met with. The technique consisted in drawing into a sterilised tube a small but fixed quantity of the fluid which was immediately centrifugalised for ten minutes. The supernatant fluid was decanted and the sediment was transferred by a fine pipette to a glass slide and allowed to dry at a temperature of 37° C. The specimen was then fixed in a mixture of equal parts of alcohol and ether, stained with hæmatoxylin and eosin or with thionin, and examined under the microscope. In normal cerebro-spinal fluid lymphocytes are altogether absent or exceedingly rare. In tabes dorsalis they are abundantly present, as also in meningeal tuberculosis, syphilitic meningo-myelitis, and in general paralysis of the insane. "Their presence is an indication of a simple process of irritation." The presence of polymorphonuclear leucocytes indicates a state of congestion or inflammation, as these elements come only from the blood-vessels by diapedesis. In syphilitic patients the occurrence of hemiplegia is followed by the appearance of lymphocytes in the cerebro-spinal fluid and the same appearance results from the growth of cerebral and spinal tumours which irritate or involve the meninges. On the other hand, in hysteria, epilepsy, neurasthenia, and typical polyneuritis there is no such lymphocytosis. "The virus of syphilis seems to have a predilection for attacking the meninges" and producing lymphocytosis. Professor Brissaud and Dr. Buandet stated in their communication that they had examined eight cases of tabes dorsalis. Seven of these were of three years' duration or less, and in all there was distinct or marked lymphocytosis. In the eighth case of tabes of 20 years' duration there was a feeble degree of lymphocytosis. Professor Babinski stated that he had examined 10 cases of tabes dorsalis and seven of general paralysis of the insane and that moderate or marked lymphocytosis was present in every case without exception. Dr. Gombault had examined 11 male and eight female cases of tabes dorsalis. In eight of these 19 cases there was abundant and confluent lymphocytosis, in two it was moderate, and in one it was absent. These last three were non-syphilitic cases of tabes. Dr. Gilbert Ballet had examined eight cases of tabes dorsalis, in five of which lymphocytosis was present. A similar condition was met with in six out of eight cases of general paralysis of the insane. Dr. Pierre Marie had examined 20 cases of tabes dorsalis of from two to 25 years' duration. In six there was abundant lymphocytosis, in 10 there was more than a moderate amount, and in three there was moderate lymphocytosis. Dr. Souques examined three cases of tabes dorsalis, in all of which abundant lymphocytosis was present The consensus of observations made by the various investigators above named tends to establish the great diagnostic value of cytodiagnosis in organic affections of the spinal cord and goes far to show that a syphilitic causation is pre-eminently a factor in the production of lymphocytosis in the cerebro-spinal fluid.

ASPARAGUS.

CLOSE upon 100 years ago—to be exact, in the year 1805—a crystalline body since called "asparagine" was first extracted from the young shoots of asparagus, which proved to be of physiological importance. Asparagine is not, however, peculiar to asparagus, it is present also in beetroot, potatoes, the shoots of peas, beans, and vetches. Although asparagine contains more than a fifth of its weight of nitrogen, yet it is probable that it has no direct nutritive value. There is reason for believing, however, that it materially aids nutrition by promoting the absorption of proteids and carbohydrates, and it also has a tendency to counteract putrefaction in the intestine. So far, however, asparagus shows no physiological or dietetic advantage over other succulent vegetables which all contain asparagine in common. Nor *is the nutritive value of asparagus greater than that of* other tender vegetables. Over 90 per cent. of asparagus is water, the rest being made up of a small proportion of fat, carbohydrate, woody matter, and mineral substances. Asparagus is probably a valuable source of mineral salts which promote a healthy alkaline condition of the blood and is also a distinct anti-scorbutic. It is doubtful, however, whether asparagus possesses any dietetic superiority over the common cabbage, seakale, or spinach, or other green vegetable so long as these are tender, while it is decidedly less nutritious than the potato. But it is the æsthetic qualities of asparagus which make it so acceptable, an agreeable flavour playing an important rôle in the great nutritive processes. As is well known, an improved appetite and a relish for food increase the activity of the digestive function

THE DISTRIBUTION OF PLAGUE.

As regards the Cape Colony the acting medical officer of health states that for the week ending May 2nd the condition of the various places mentioned below was as follows: At the Quarantine Station, Saldanha Bay, 2 Asiatic males remained under treatment in the hospital, both being convalescent At Port Elizabeth 4 cases of plague have been discovered—namely, 1 European female (found dead), 1 native male on April 28th, and 2 native males, one of whom was found dead, on May 2nd. At the Plague Hospital, Port Elizabeth, 1 European male, 1 coloured female, and 1 native male were discharged cured during the week, leaving 13 cases under treatment. Plague-infected rats continued to be found in the town during the week. At East London 2 cases of plague were discovered during the week—namely, 1 native male on April 30th and 1 native female on May 2nd. At the Plague Hospital a native male died during the week, leaving 2 cases under treatment. At King William's Town 4 cases of plague were discovered during the week—namely, 1 native male on April 26th, 1 native female on the 27th, 1 native male (found dead) on the 30th, and 1 European female on May 2nd. At the Plague Hospital 1 native male and 1 native female died during the week, leaving 5 cases under treatment At Graaff-Reinet and Burghersdorp no cases of plague and no plague-infected rats were found during the week, but at Queenstown plague-infected rats were discovered at the railway goods-shed. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on May 22nd states that for the week ending May 21st there were 2 cases of plague, of which 1 proved fatal.

HUDDERSFIELD WORKHOUSE NURSING.

IN order to render less inefficient the nursing of the sick poor in workhouses a departmental committee recently recommended that a superintendent nurse should be appointed who should have general control of the sick wards instead of the master and who should exercise with the master a dual control over paid and pauper servants. These suggestions have been under the consideration of the Huddersfield board of guardians and a committee has proposed certain modifications which serve to call attention to the difficulties of the position but do little towards overcoming them According to the scheme of the board the master or matron is to be in charge of the whole establishment, including the sick wards, and is to be intrusted with the duty of reporting to the guardians any neglect on the part of the superintendent nurse. The nurse, however, is to be responsible to the medical officer for the welfare and nursing of the sick. The matron is to look after the cooking of food for the sick and their nurses and after the making, mending, and washing of clothes and linen for the use of the sick. Stated broadly, the position will amount to this—the *matron will be at once the superior officer of the* superintendent nurse and her cook and washerwoman. As compared with the matron the superintendent nurse will almost of necessity be a woman of higher education and quite possibly, outside the workhouse, of higher social grade. Moreover, the matron will be very frequently the wife of the master. Clearly, then, the opportunities for bickering and friction already available will be considerably increased and it is too much to hope that they will not be utilised. Stress is very properly laid by the Huddersfield board upon the desirability of separating the sick wards, and incidentally the superintendent nurse, from the main building and its guiding spirit, the matron; but this would be only a partial remedy. The only rational plan is to make the superintendent nurse responsible to the medical officer and to him alone. This is an arrangement which a nurse is accustomed to and understands, and it is one which experience has shown—for instance, in the case of the infirmaries in London—to be advantageous to all concerned.

THE DIRTY FOUNTAINS IN TRAFALGAR-SQUARE.

A FOUNTAIN is associated in most people's minds with the idea of purity, as something that is clear, bright, and sparkling, and as a matter of fact its function may be considered to be threefold: in the first place a fountain of water is pleasing to the eye; in the second place it cools the air; and in the third place it exercises certain important purifying effects upon the air. The fountains of Trafalgar-square, however, according to our examination possess none of these qualifications; indeed, quite the reverse would appear to be the case. For example, on the eighteenth day of the present month we observed that the temperature of the air in the square averaged 54° F., while the water of the fountains at the same time showed a temperature of over 72°. It seems pretty clear, therefore, that the water of the fountains is relatively speaking, warm and we have noticed on several occasions on a cool evening a cloud of vapour over the surface of the pools such as would be given off by warm water in a cold place. The fountains therefore are not likely to have a cooling effect upon the air. Next it may be observed at the point where the stream of water takes a curve outwards that the water is always of a dirty greenish-yellow colour. The indications so far are that the water is not as clean as it might be. Why it is warm we do not know unless it consists of the exhaust water from a steam-engine, or, as has been suggested, the waste water of some adjoining public baths or laundry. Subsequently we considered that it would be interesting to make a chemical analysis of the water and the results ultimately obtained were as follows: total solid matters, 42·00 grains per gallon; inorganic residue, 35·00 grains per gallon; chlorides, calculated as common salt, 12·70 grains per gallon; total hardness as calcium carbonate, 6·40 grains per gallon; free ammonia, 0·0084 grain per gallon; albuminoid ammonia, 0·098 grain per gallon; nitrates, *nil;* nitrites, traces; and phosphates, distinct traces. On evaporation the water yielded a dirty-looking residue which charred strongly on heating, giving off at the same time a bad smell. Microscopical examination showed pond-water organisms, epithelial scales, and fungus mycelium. The colour of the water was a dirty yellowish-green The specimen which we obtained on being kept in a closed bottle developed an offensive musty odour and became opalescent in a few days A water showing such results as these would, of course, be unhesitatingly condemned for drinking purposes. We maintain, however, that it is desirable from a public health point of view that the water of these fountains should be as pure as that of a drinking supply. We have seen it stated, by the way, that there are artesian wells at Trafalgar-square which supply the Houses of Parliament. We hope that the source of this supply is not identical with that of the water used for the fountains in Trafalgar-square or if so that it is not used for drinking purposes by Members of Parliament. The water is both chemically and physically dirty, exhibiting a strong degree of pollution if judged by a drinking-water standard. It is not unreasonable to suggest that the spray blown about by the wind might easily be inhaled by the passers-by with mischievous results. Surely it is not too much to expect that what the great Sir Robert Peel called "the finest site in Europe" should be provided with fountains the water of which is absolutely free from reproach. We have often pointed out that water in its passage through air, as in the case of rain, plays an important function: the air is cooled, cleaned, and freshened. We are certain that nothing of the kind can be effected by the dirty waters of the Trafalgar-square fountains at the present time; on the contrary, the air is more likely to be vitiated by their action.

LUNACY IN SCOTLAND.

THE forty-fifth report of the Commissioners in Lunacy for Scotland, issued in February, 1903, states that on Jan. 1st, 1903, there were in Scotland 16,658 insane persons under the official cognisance of the commissioners Of these, 2416 were private patients maintained from private sources, 14,191 were maintained by parochial rates, and 51 at the expense of the State. As the total number of lunatics on Jan. 1st, 1902, was 16,288, an increase had taken place during the year 1902 of 370. A review of the statistics from 1858 to 1903 shows that when the Board of Commissioners in Lunacy entered on its functions in 1858 the total number of lunatics officially known to the board was 5824, showing an increase of 10,834 during the subsequent 44 years ending Dec. 31st, 1902. In other words, since 1858 the number of lunatics under the jurisdiction of the board has increased by 186 per cent. The increase of the population during the same period has been 50 per cent. The average annual increase of pauper patients in establishments during the past 10 years has been 300. During the past year the increase was 374, being 74 in excess of the average. In the year 1893 the proportion of pauper lunatics to the population in Scotland was 240 per 100,000. This proportion, however, has been steadily rising since then and stands now at 250 per 100,000. The number of pauper lunatics in private dwellings has increased during the past ten years from 2519 to 2642. The proportion to population of private patients under care in private dwellings has remained unchanged for many years. Among lunatics are included imbecile children in training schools, but the number of the children is the same as in the previous year. The number of private patients admitted to institutions during the year was 548, being ten more than in the preceding year and six more than the average for the quinquennium 1895-99. The number of pauper patients admitted was 3113, being 151 more than the number during the preceding year and 374 more than the average for the quinquennium 1895-99. The number of all patients discharged as recovered from institutions during the year amounted to 1620, or 12·2 per cent. of the average number resident. The deaths during the year amounted to 1201, or 9·1 per cent., as calculated on the same basis. An elaborate inquiry into the extent and distribution of insanity in the various shires and districts of Scotland correlated with the census returns of 1901 shows that the proportion to population of persons of unsound mind varies very greatly, the highest proportion being in Argyll and the lowest in Dumbarton. The ten highest proportions stand in descending order as follow: Argyll, 842 lunatics per 100,000 population; Sutherland, 775; Ross and Cromarty, 767; Nairn, 745; Caithness, 720; Inverness, 705; Orkney, 680; Shetland, 675; Bute, 650; and Perth, 602. A study of the returns shows that at the top of the list stands without a break "the whole Highland and insular region of

Scotland, mainly rural and non-industrial," and at the foot stands "central Scotland, which is mainly urban and which whether urban or not offers the best field for those in search of employment." As the result of elaborate collation and comparison of facts the commissioners conclude that the somewhat startling result is shown that where alcoholic excess and other forms of vice are with good reason supposed to be least common and where life is most free from worry, strain, and excitement insanity is most prevalent (as in the ten districts above mentioned) while, on the other hand, where drink, vicious living, worry, and stress are all at their highest—viz., in the counties of Fife, Ayr, Lanark, Stirling, Renfrew, Linlithgow, and Dumbarton—the prevalence of insanity falls to the lowest point. A closer consideration of the facts and circumstances affecting these two extreme groups tends, however, to raise doubts as to whether the southern group possesses inherently all the advantages in respect to sanity which the bare figures seem to give it, while support is lent to the view that the evil effect of the intermarriage of predisposed persons is to a large extent an important factor in the prevalence of insanity in the northern group.

PRESERVING EGGS WITH SILICATE OF SODA.

MORE than once in these columns we have drawn attention to the excellent method of preserving eggs by means of submerging them in a 10 per cent. solution of silicate of soda or water-glass. Several readers have since written to us asking for further information as regards the practical details of the method. We believe the following plan gives quite satisfactory results. One pound of water-glass (which can be obtained from the pharmacist) should be carefully dissolved in one gallon of cold water. It will take some time to incorporate the treacly silicate with the water but the mixing must be done thoroughly. The solution with the eggs placed in it should be kept in an earthenware glazed jar. The eggs should be packed point downwards and completely submerged. Any loss of the solution by evaporation should be made up by adding a little water from time to time. Should any of the eggs float a common dinner-plate should be sunk below the surface of the fluid so as to rest inverted on the eggs. The shell should be pierced just before the egg is boiled, otherwise the egg might burst. The plan is so simple and effectual, eggs keeping as good as fresh for close upon a year, that there is no reason why it should not be universally adopted, more especially when eggs are plentiful and cheap.

THE CONTROL OF INEBRIATES.

THE recently published report of the Dalrymple Home established by the Homes for Inebriates Association is instructive and on the whole encouraging. From a summary of results obtained since the home was opened 19 years ago it appears that 679 persons have been under treatment during this period, the average term of residence being six and a half months. Of these 679, 241 are stated to be now doing well and 100 to have improved. On the other hand, 203 have not improved, while particulars are wanting as to 78. Nine have become insane, 48 have died, and 83 have been re-admitted. Thus, while we are unable from the data before us to decide how much, if at all, the total of success absolutely exceeds that of failure, the proof, so far as it goes, indicates a margin on the right side. At all events we have the assurance that about a third of the cases treated have resulted in more than transient amelioration. When viewed in its domestic relation the benefit which these figures illustrate is magnified. The advantage to the inebriate, desirable in itself, is a small matter in comparison with the present comfort and the future hope which even his mere absence implies for those of his family circle. In the event of his reformation the gain to all concerned is incalculable. So far the provision made by legislation for the restraint of the drunkard is limited (1) to the case in which he is himself willing for a time to endure the loss of liberty; and (2) to the case in which he has forfeited this by conviction in a court of law. There is, however, another and a much larger class of inebriates who are not controllable on either of these grounds and who are yet undoubtedly and habitually drunken and in whom apparently there exists no inherent remnant of the curative will-power. The right of personal freedom is surely no privilege but a wrong to such persons and through them a wrong to society. It has become practically an obstacle to their recovery by means of that salutary restraint from without which is one of the most trustworthy remedies, if not the only one, revealed to us by experience It is worth considering whether there should not be applied to the treatment of such cases in this country some system akin to the French *conseil de famille*. There is little likelihood of abuse under such an arrangement, carried out as it would be under supervision of the magistracy.

THE annual meeting of the Medico-Psychological Association of Great Britain and Ireland will be held on July 16th and 17th and not as previously announced. The meeting will be held at 11, Chandos-street, Cavendish-square, London, W.

THE foundation-stone of the Winsley Sanatorium will be laid by Lady Dickson Poynder on Thursday, June 4th, at 3.30 P.M. The nearest railway station to Winsley is Limpley Stoke on the Great Western Railway.

OWING to the great pressure on our space this week caused by the report of the proceedings of the General Medical Council we are compelled to postpone the publication of several important communications.

LEPROSY AND FISH-EATING.

THE discussion on the address by Mr. Jonathan Hutchinson on the results of his recent journey to India for the investigation of leprosy was held at the Medical Graduates' College and Polyclinic, Chenies-street, London, on May 21st

The chair was taken by Dr. H. RADCLIFFE CROCKER and the proceedings commenced by Mr. JONATHAN HUTCHINSON pointing out that the standing committee on leprosy of the Medical Graduates' College and Polyclinic should institute an inquiry by means of systematic correspondence into the question of the causation of leprosy by eating fish. He thought that if such a correspondence were instituted it would be found that wherever Roman Catholic missionaries were successful there leprosy was abundant. He asked if leprosy was a disease spreading from person to person why it should pick out the Christians in India out of all proportion to the Hindoos. It must be because of the change in the kind of food eaten and that must be the fish.

Mr. M. I. FINUCANE (late of Fiji) stated that in his opinion leprosy might be caused by other agencies than the eating of fish and he instanced the dirt and filth in which the coolies in Fiji lived. He supported Mr. Hutchinson in regard to the insanitary conditions of life that accompanied the conversion of natives to Roman Catholicism He thought that the standing committee of the Polyclinic on leprosy should take up the matter of the segregation of lepers, for upon that point the Government was continually pressing medical officers concerned for advice and direction.

Dr. H. D. MCCULLOCH (Secunderabad) said that in Cashmere there were two great classes of people—those who lived in the valleys, whose diet consisted of fish, and those who lived a nomadic life on the *mountains living* chiefly on a vegetable diet. He asserted that it was an almost impossible thing for the mountaineers to procure fish, as suggested by Mr. Hutchinson, but it was from this class that cases of leprosy came and not from the people who lived in the valleys and ate fish throughout the year.

Dr. P. S. ABRAHAM, after complimenting Mr. Hutchinson on the work he had done, proceeded to give in detail his reasons for dissenting from the conclusions arrived at by Mr. Hutchinson He produced some cuttings from the daily papers in which it was stated that Mr. Hutchinson had declared that on the whole the commission on leprosy had reported favourably on his fish theory of the causation of leprosy.

Mr. HUTCHINSON stated that what he said was that because the commission on leprosy found patients in the leper asylums who said they had not eaten fish, therefore the commission had reported somewhat unfavourably upon his fish theory, but he still contended that the commission on the whole was favourable to it in spite of its somewhat adverse verdict.

Dr. ABRAHAM expressed his opinion that Mr. Hutchinson ought to put the misunderstanding right in the press because on p. 339 of the report of the commission it was distinctly stated that in the opinion of the commission there was no doubt that the consumption of fish was not the cause of leprosy.

Dr. C. J. S. HANCOCK (Assam) communicated some interesting details concerning the consumption of fish by all classes in Upper Assam.

Dr. C. AFFLECK discussed the question of leprosy in Scotland in the Middle Ages and gave in some detail the opinions of his medical teachers concerning Robert Bruce and other matters. He advised the committee to seek for an elucidation of the question by investigating the fish theory.

Dr. CROCKER said that undoubtedly the whole subject depended upon the demonstration of the lepra bacillus in fish and until that was done he could see but little use in prolonged discussions except in so far as they tended to lead investigators in the direction of seeking for the lepra bacillus.

Mr. HUTCHINSON, in reply, deprecated the contention of Dr. Crocker that to prove his fish theory the bacillus must be demonstrated in the fish, because he thought that many things could be, and were, proved before they were actually demonstrated. In respect to the Cashmere mountaineers he explained that the circumstances were somewhat similar to those noticed in South Africa, where the labourers up country who subsisted on salt fish contracted leprosy, but the fishermen at Cape Town who supplied the fish were practically exempt, the explanation being that they consumed the fish when it was fresh and wholesome.

The meeting then terminated.

THE ASSOCIATION OF CERTIFYING FACTORY SURGEONS.

THE gatherings of the Certifying Surgeons' Association have usually taken place in the Midlands. This year, however, a well attended dinner was held in London at the Hotel Cecil on May 22nd. Considerable regret was felt at the enforced absence of the Home Secretary who had accepted an invitation to be present, but among the guests of the association were numerous representatives of the Home Office connected with the Factory Department, and Sir Kenelm Digby, Permanent Under Secretary of State for the Home Office, filled the seat that Mr Akers-Douglas should have occupied. Dr. T. F. Young of Liverpool, President of the association and chairman of the dinner, after the usual loyal toasts had been drunk proposed "The Home Department of His Majesty's Government," and referred in his speech to the progressive nature of the work instituted under, and forwarded by, the Factory Department of the Home Office, making a happy reference to the wealth of a nation consisting in the numbers of its healthy population He alluded to Dr. B. A. Whitelegge, chief inspector of factories, who was present, as one of the greatest public benefactors whom he could name. In his reply on behalf of the Home Office Sir Kenelm Digby dwelt upon the great and increasing development of the Factory Department and upon the far-reaching effect of the work done throughout the kingdom by the certifying surgeons, not only in populous manufacturing districts but in others where there were few factories and considerable distances had to be traversed by those responsible for the health of the workers in them. Professor C. J. Wright of Leeds proposed the toast of "The Factory Department of the Home Office," coupling with it the name of Dr. Whitelegge which was received with well-deserved enthusiasm. Dr. Whitelegge, in replying, spoke of the enormous growth of the department under his supervision, to the spread of its jurisdiction from land to water, from docks to harbours, and made a good point when he expressed regret that although accidents that took place were recorded no statistics could show the number of accidents prevented. In replying to the toast of his own health, which Dr. Whitelegge had proposed, Dr. Young referred to the difficulty which met the certifying surgeon when he knew that an opinion adverse to the employment of a young person at a factory might mean loss of all power to earn a livelihood. He exhorted his hearers to let their humanity influence them in such cases wherever doubt arose and pointed out that the boy who was unfit owing to physical infirmity for a particular duty for which he had been engaged, might still be found work in some other part of the same factory in different circumstances, if the certifying surgeon would explain to the employers the nature of the work likely to prove injurious to him.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THIS society held its annual meeting at 11, Chandos-street, London, on May 20th, and the opportunity was taken by Mr. Christopher Heath, who occupied the chair, to draw the attention of the profession to some important points in connexion with the advantages offered by the society. After congratulating the members on the excellent financial position of the society Mr. Heath proceeded to explain how much good the society was doing and how much more it could do if its benefits were more generally appreciated by medical men. The best proof of what might be done could be gathered from a study of the voting-paper issued by the Royal Medical Benevolent College for the forty-ninth election of pensioners and foundation scholars. On looking through the list of candidates for the five vacant pensions to see how many of the applicants would have been eligible to receive benefit under the rules of the Society for the Relief of Widows and Orphans of Medical Men, Mr. Heath noticed that there was an application from the widow of a medical man who had practised for nine years in Battersea and Queensland. That widow was 63 years of age, with very limited means, but if her husband had taken advantage of the benefits of the society she would have received immediate assistance, because the fact that her husband had died in Queensland would not have rendered [illegible] relief. Curiously enough, two [illegible] had to deal with a very similar [illegible] usband had died in Australia, [illegible] ily; happily for the widow, before that gentleman went out to Australia he had become a subscriber to the Society for the Relief of Widows and Orphans of Medical Men and had kept up his subscription. The society granted that lady £50 a year and an allowance for each of the children, the total amount that she received annually from the society being £125. This case certainly served as an excellent example of the benefits that any medical man might secure for his family by joining the society and paying two guineas yearly.

It was worthy of the widest circulation that a life-membership of the society could be secured by the one payment of 20 guineas up to 30 years of age, 25 guineas up to 40 years of age, and 30 guineas after that. It was certainly a matter of regret that in spite of this admirable means of making timely provision for widows and orphans, so few medical men were found availing themselves of this opportunity of discharging a part of their duty [illegible]. Mr. Heath referred to th [illegible] affliction applying to the R [illegible] and pointed out that it wa [illegible] thing that happened every year. The Society for the Relief of Widows and Orphans of Medical Men had no power to make any grant whatsoever except to the widows and children of those who had been subscribers, but it was only too happy to relieve the wants of the widows and orphans of those gentlemen who had taken the opportunity of becoming members of the society and had fulfilled the conditions required by the regulations. The society was in the possession of the necessary funds and no one entitled to relief was ever sent away because there was no money available. Pecuniary resources were at the disposal of the society in abundance; its funds were large and well invested.

Mr. S. Felce, a vice-president of the society, remarked that for a medical man to say he would not join the society because it did not need assistance and because he thought his wife and children were never likely to want, was an argument that was not borne out by the facts of everyday life, for it was a matter of common knowledge that misfortune might happen to the most prosperous, and no one knew when those near and dear to him might need assistance.

MEDICINE AND THE LAW.

The Dying Declaration.

At the trial for murder of a man named Bottomley at Liverpool considerable discussion seems to have taken place as to the admissibility of statements made by the woman whose death he had caused. He was charged with killing her by procuring, or attempting to procure, abortion and in these cases, where the woman is not infrequently attended by a medical man before death takes place, this question of statements made by the patient often arises and medical men should be aware of it. In cases of homicide it is the practice to admit testimony as to the dying declarations of the deceased with respect to the cause of his death, it being first shown that such declarations were made under a sense of impending dissolution. It is for the judge to be satisfied that the deceased when making the statement had a "settled hopeless expectation of death" before he admits the evidence. In all cases—that is to say, in other cases as well as in those of homicide—depositions of a deceased witness may be read, but these have to be properly taken in the presence of a magistrate and with the observance of other formalities which need not be gone into. The dying declaration, as it is usually called, is simply the statement of a person who with the expectation of death before him would not be likely to say what was not true. It is right in such a case for anyone present who can do so to make immediately an accurate note of what the deceased said and to include in the note any question which may have evoked the statement thus made. A note should also be taken of anything said by the deceased which bears on the question of his knowledge that he is dying.

The Word of a Medical Man.

The *Times* report of the recent trial of seamen for the murder of their officers on board the *Veronica* contained the following passage: "Yesterday the resumption of the trial was delayed owing to the illness of a juryman. A new juror was eventually sworn and the evidence was read over. There is precedent for procedure of this kind even in a murder trial,...... but the more usual and, indeed, the correct, course appears to be that the illness of the afflicted juror and his incapacity to serve should be proved on oath in open court and not taken for granted on the bare assurance of a doctor." Writing in the *Times* of May 16th Sir Herbert Stephen, clerk of assize for the Northern circuit, emphatically contradicted a statement which is certainly not in accord with the experience of most medical men. Sir Herbert Stephen wrote: "The only purpose of an inquiry by sworn evidence as to the missing juryman's condition is to ascertain whether anyone ought to be made penally responsible for the separation of the jury. There was no reason in this case for any such inquiry." A medical man is sworn to give evidence where an issue is being tried and he then gives evidence like any other witness. There are occasions, however, when no oath is required and the word of a member of a learned and honourable profession is accepted without question. The statement of a barrister is also accepted on many occasions in courts of law, although as a witness he is put upon his oath like anyone else. The authority of Sir Herbert Stephen, who wrote as clerk of assize of the Northern circuit, will be sufficient to satisfy everyone that the correct procedure was adopted on the occasion in question.

Unqualified Practice.

A man named Thomas Dixon was summoned recently before Mr. Denman at Marlborough-street Police-court and fined £10 with £10 10*s*. costs, or in default two months' imprisonment, for an infringement of the Medical Acts. It was proved that he had examined the pulse and tongue of a witness (who was a clerk in the office of the solicitor to the Medical Defence Union and had nothing the matter with him), had sold him a bottle of medicine, and on being asked to give a certificate had signed it "Dr. R. Cowen." Mr. R. J. Cowen of 25, Clarges-street, W., stated that the defendant had been his assistant and had been discharged for acting in his absence in the way in which he had. As the only defence seems to have been an appeal in mitigation of punishment to the effect that the defendant had been employed as an assistant to medical men for 18 years, but was "one of the unfortunate ones who had not succeeded in passing his examination," the penalty inflicted does not seem excessive. If the public are to be treated by unfortunate ones who cannot pass their examinations they are at all events entitled to be protected against being misled by any pretence of qualification.

A Judge upon the Sale of Pistols.

At the recent trial of a young man named Platell at the Old Bailey for a murder committed at Blackheath the medical evidence bearing upon the prisoner's mental condition was conclusive and the jury found him guilty but insane at the time of the commission of his act. He appears to have bought a revolver and 50 cartridges at a pawnbroker's shop for 10*s*. 3*d*. and to have proceeded the same night to shoot at, and to wound, a policeman at close range, afterwards shooting at, and killing, an unfortunate man who, joining the hue and cry, sought to apprehend him. A Mrs. Jennings, who had refused to sell the prisoner a revolver earlier in the evening because she believed him to be drunk, was warmly commended by the judge. On the other hand, the pawnbroker who afterwards sold the fatal weapon is reported to have been thus addressed by Mr. Justice Grantham: "In my judgment you ought to be in that dock charged with manslaughter. When a man loads a revolver for another who is drunk and that person goes and shoots another it is a serious question whether the man who loads the revolver is not guilty of manslaughter." This may be the case, and no doubt if the pawnbroker had any reason to believe that his customer was drunk when he asked for the pistol, it is proper that he should be rebuked. At the same time, the mere selling of a revolver for a few shillings to a stranger who may be mad, or a drunkard, or a criminal, is perfectly legal, and so is the act of showing a novice how to load a dangerous weapon. If the law made the whole trade in cheap pistols impossible and only allowed the sale of revolvers to persons able to prove some reasonable claim to possess them many lives would be saved in every year. The Bill at present before Parliament would restrict the sale of pistols to persons producing a 10*s*. gun licence and giving their names and addresses at the time of purchase. Whether this would have affected the case of Platell by preventing the sale to him of the weapon in question depends more upon how much money he had in his pocket than upon anything else. He was of respectable parentage and appearance and under the conditions hitherto existing the issuing to him of a gun licence would have been merely a question of his ability to pay for it.

General Sir Hector Macdonald Memorial.—A gentleman has intimated that when the subscriptions to the London memorial amount to £4000 he will give a donation of £1000 and yet a further sum in proportion to the total amount subscribed. Dr. Farquhar Matheson, J.P., 11, Soho square, W., and Mr. William Grant, St. Mildred's House, Poultry, E.C., the honorary treasurers, will be glad to acknowledge all donations.

Devon and Cornwall Ear and Throat Hospital, Plymouth.—The annual meeting of the subscribers to this institution was held on May 18th under the presidency of the mayor. The financial statement showed a favourable balance of £20, but there still remains a debt of £1200 on the building. During the year a new ward has been added to the hospital. The medical report stated that 851 patients were treated during 1902, compared with 664 in 1901, and that 222 operations were performed.

Looking Back.

FROM

THE LANCET, *SATURDAY*, MAY 28, 1825.

MORE "HOLE AND CORNER" DOINGS.[1]

Comical as we know Mr. Abernethy to be, we did not expect, after we had *concluded* the publication of his lectures, after we had presented the *last* of them to the world, that he would call upon the Chancellor to prevent our *doing that* which had actually been *done* several weeks previously; but it appears that Mr. Abernethy's notion of law is, that it can alter the past as well as the future.

He may possibly have vanity enough to suppose that we shall *reprint* his lectures. On this point his mind may be perfectly at ease; our pages have been already obscured with his hypothetical nonsense during six tedious months, and when we read the proof of the last paragraph we felt relieved as we formerly stated, of a most tolerable *incubus*

This renewed attack is one of a series of legal proceedings which the "Hole and Corner" people long ago resolved upon instituting against THE LANCET, with a view of deterring us from dischargi [illegible] subduing that [illegible] have proclaime [illegible] We have hitherto smiled at their impotent efforts, and smile at them still; for really their imbecility renders them the most ludicrous of opponents. We sometime since alluded to a meeting of certain [illegible] held for the purpose o [illegible] have the effect of *putt* [illegible] tion on this subject was exceedingly loose until Wednesday last, when, having heard it whispered that one or more of those meetings had been held at the Freemasons' Tavern, it struck us that we might, by a little manœuvre, get possession of the secret; knowing how fervently the "Hole and Corner" people worship the molten god, we considered it extremely probably, (as they had met on such a disastrous subject,) that they had forgotten to pay their bill. Now, as the meeting was held on our account, we thought it but right that we should go to the landlord of the tavern—ask how matters stood, and, if unpaid, offer to settle the account.

It is not a little extraordinary that our conjecture was realised. We informed Mr. Cuff's clerk, without any preliminary observation, that we had called to pay the expences of a Meeting of Medical Gentlemen, friends of Mr. Abernethy, which had been held there in December last—"Oh yes, sir, said he, I recollect, one Saturday night in that room."—(Pointing to a room at the bottom of the stairs; a low situation, calculated for *low* company and *low* deeds)—"The account is not settled, we believe?" "No, it is not." "If you will get it drawn out, as we see you are busy now, we will call and pay it in the morning." The following morning we were punctual; obtained the bill, paid it, and presented the waiters with 2*s* 6*d*, for they had been forgotten too One of the gentlemen was so affected that he was compelled to have a coach to take him away. The landlord paid the coachman, which was also forgotten. This *Tavern account* of a Meeting of Gentlemen is really so rare—so choice a morsel, that we must present our readers with a faithful transcript of it:—

Mr. STANLEY,

To J. J. Cuff,

1824.		£	s.	d.
Dec. 27.	To room		15	0
	Paid for coach		1	0
			16	0
	Waiters		2	6
May 25.			18	6

Recd for J. J Cuff,
T. Hoggray

Here was a jovial meeting! Look at the charges for refreshments! Not a solitary glass of Burgundy or of Mr. Cuff's fine old Port. The only thing inquired for was a preserved peach by Mr. Travers, but when that gentleman had made the lateral incision and found that it was *stoneless*, he rejected it with apparent nausea; however upon its being represented to him, shortly afterwards, that one of the waiters had discovered the stone in an old *musk box*, he became somewhat better, and soon after left the room. Mr. Cuff, we should suppose, from the appearance of this bill, cannot wish to have another Medical Meeting. It was a "Hole and Corner" proceeding to the very letter, for it appears, by the bill, that although it took place at the latter end of December there was neither fire nor candle.

Mr. Green, we understood, ordered the room, but who attended besides that gentleman, Stanley, Travers, Brodie, and Vincent, we cannot say. Mr. Stanley, we expect, will [illegible] any little bill, and we have [illegible] grateful to us for having [illegible] specially as the cause for which it was incurred is one which does him and his coadjutors so much honour. We ought to have stated, that this meeting was convened by letter, addressed to nearly all the Hospital Surgeons and Lecturers.

Who can *now* doubt that we have been the objects of a conspiracy, and that these repeated law proceedings are systematic attacks, which it is hoped, (vainly enough, God knows,) will ultimately conquer us?

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9018 births and 4490 deaths were registered during the week ending May 23rd. The annual rate of mortality in these towns, which had been 17·5, 15·9, and 15·4 per 1000 in the three preceding weeks, rose again to 15·5 per 1000 last week. In London the death-rate was 14·8 per 1000, while it averaged 15·8 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 3·2 in Hastings, 8·5 in East Ham, 8·6 in Hornsey, 9·1 in Handsworth, 9·8 in Walthamstow, in Kings Norton, and in Aston Manor, and 10·0 in Tottenham and in Stockton-on-Tees; the highest rates were 20·2 in Sheffield and in Swansea, 20·3 in Manchester and in Salford, 21·8 in Wigan, 21·9 in West Bromwich, 22·0 in Sunderland, 22·2 in Grimsby, and 24·7 in Huddersfield. The 4490 deaths in these towns last week included 461 which were referred to the principal infectious diseases, against 519, 457, and 428 in the three preceding weeks; of these 461 deaths 146 resulted from measles, 102 from whooping-cough, 66 from diarrhœa, 57 from scarlet fever, 46 from diphtheria, 32 from "fever" (principally enteric), and 12 from small-pox. No death from any of these diseases was registered last week in Hornsey, Hastings, Bournemouth, Reading, Devonport, Burton-on-Trent, Handsworth, Kings Norton, Wallasey, Warrington, Bury, Barrow-in-Furness, or Tynemouth; while they caused the highest death-rates in Great Yarmouth, Hanley, West Bromwich, Smethwick, Oldham, Sheffield, Middlesbrough, Merthyr Tydfil, and Swansea. The greatest proportional mortality from measles occurred in Wolverhampton, West Bromwich, Salford, Sheffield, Middlesbrough, and Swansea; from scarlet fever in Great Yarmouth, Huddersfield, and Merthyr Tydfil; from diphtheria in Hanley; and from whooping-cough in West Ham, Smethwick, Grimsby, Oldham, Sheffield, and Rotherham. The mortality from "fever" showed no marked excess in any of the large towns. Of the 12 fatal cases of small-pox registered in these towns last week six belonged to Liverpool and one each to Leicester, Oldham, Burnley, Bradford, Leeds, and Gateshead. The number of small-pox patients in the Metropolitan Asylums hospitals, which had been 60 at the end of each of the two preceding weeks, had increased to 64 at the end of last week; 19 new cases were admitted during the week, against 12, 17, and seven in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday, May 23rd, was 1759, against numbers increasing from 1662 to 1755 on the five preceding Saturdays; 234 new cases were admitted during the week, against 235, 229, and 236 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 283, 260, and 225 in the three preceding weeks, further declined last week to 182, and were 34 below the number in the corresponding period of last year. The causes of 48, or 1·1 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Bolton, Salford, Newcastle-on-Tyne, and in 44 other smaller towns; the largest proportions of uncertified deaths were registered in Hanley, Smethwick, Barrow-in-Furness, Sheffield, and South Shields.

---

[1] Excerpt from remarks by the Editor of THE LANCET.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 19·2, 17·9, and 18·0 per 1000 in the three preceding weeks, declined again to 17·2 per 1000 during the week ending May 23rd, but showed an excess of 1·7 per 1000 over the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·4 in Dundee and 14·6 in Edinburgh to 18·6 in Glasgow and in Perth and 23·3 in Greenock. The 563 deaths in these towns included 22 which were referred to whooping-cough, 16 to diarrhœa, six to measles, three to diphtheria, three to "fever," and one to scarlet fever, but not one to small-pox. In all, 51 deaths resulted from these principal infectious diseases last week, against 57, 57, and 68 in the three preceding weeks. These 51 deaths were equal to an annual rate of 1·6 per 1000, which corresponded with the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 32, 26, and 25 in the three preceding weeks, further declined last week to 22, of which 13 occurred in Glasgow, three in Edinburgh, three in Greenock, and two in Leith. The deaths from diarrhœa, which had been 11 and 12 in the two preceding weeks, further rose to 16 last week, and included 10 in Glasgow, two in Dundee, and two in Aberdeen. The fatal cases of measles, which had been seven, eight, and 16 in the three preceding weeks, declined again last week to six, of which three were registered in Glasgow and two in Edinburgh. The deaths from diphtheria, which had been five and six in the two preceding weeks, declined again to three last week and all occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 125, 104, and 101 in the three preceding weeks, increased to 102 last week, and were 54 below the number in the corresponding period of last year. The causes of 13, or more than 2 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·7, 25·3, and 22·3 per 1000 in the three preceding weeks, rose again to 22·4 per 1000 during the week ending May 23rd. During the past four weeks the death-rate has averaged 23·9 per 1000, the rates during the same period being 15·6 in London and 16·4 in Edinburgh. The 163 deaths of persons belonging to Dublin registered during the week under notice were within one of the number in the preceding week and included 11 which were referred to the principal infectious diseases, against 15 in each of the two preceding weeks; of these four resulted from small-pox, two from "fever," two from diarrhœa, and one each from measles, scarlet fever, and whooping-cough, but not one from diphtheria. These 11 deaths were equal to an annual rate of 1·5 per 1000, the death-rates last week from the same diseases being 1·7 in London and 1·0 in Edinburgh. The fatal cases of small-pox, which had been four in each of the two preceding weeks, were again four last week. The mortality from both "fever" and diarrhœa was slightly in excess of that recorded in the preceding week, while the deaths from measles and whooping-cough showed a decline. The 163 deaths in Dublin last week included 27 of children under one year of age and 41 of persons aged 60 years and upwards; the deaths both among infants and elderly persons last week were slightly fewer than in the preceding week. Six inquest cases and seven deaths from violence were registered, and 59, or more than a third, of the deaths occurred in public institutions. The causes of seven, or more than 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeons: A. H. L. Cox to the *Pembroke* for the *Northumberland*. Surgeons: A. W. Iredell, W. K. D. Breton, F. C. Robinson, C. H. Dawe, C. E. C. Child, R. Thompson, W. A. Illingworth, M. T. Male, R. Kennedy, J. H. L. Page, J. J. H. Rooney, E. S. Wilkinson, W. E. Ormsby, E. A. G. Wilkinson, and A. F. Fleming to the *Duke of Wellington* for Haslar Hospital. Civil Practitioners: S. Copley to be Surgeon and Agent at Boyne and Clogher Head, and G. Byres at Belhelvie, N.B.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel G. D. Bourke to be Colonel, vice W. J. Fawcett, promoted (dated April 1st, 1903); Lieutenant-Colonel E. V. A. Phipps retires on retired pay (dated May 27th, 1903).

Surgeon-General J. A. Clery, C.B., Principal Medical Officer at Pretoria, has arrived home.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major R. S. Smith having resigned his appointment in the Volunteers ceases to be an officer in the Army Medical Reserve of Officers.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Manchester Companies: Lieutenant W. M. Steinthal to be Captain. Dated May 27th, 1903.

VOLUNTEER INFANTRY BRIGADE BEARER COMPANY.

Devon: Lieutenant H. W. Webber to be Captain. Dated May 27th, 1903.

ROYAL ARMY MEDICAL CORPS (MILITIA).

Captain A. R. H. Oakley resigns his commission. Dated May 27th, 1903.

The promotion of Lieutenant H. E. Dalby to the rank of Captain, which was announced in the *London Gazette*, dated May 5th, 1903, bears date March 28th, 1903, and not as therein stated.

IMPERIAL YEOMANRY.

Gloucestershire (Royal Gloucestershire Hussars): Surgeon-Captain H. Bramwell to be Surgeon-Major. Dated May 20th, 1903. Lothians and Berwickshire: Surgeon-Major T. F. S. Caverhill to be Surgeon-Lieutenant-Colonel. Dated May 20th, 1903. Pembroke: Surgeon-Lieutenant-Colonel G. R. T. Phillips resigns his commission and is granted the honorary rank of Surgeon-Colonel, with permission to wear the uniform of the regiment on retirement. Dated May 20th, 1903. Worcestershire (the Queen's Own Worcestershire Hussars): Surgeon-Lieutenant J. H. Beilby to be Surgeon-Captain. Dated May 20th, 1903.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 2nd Sussex: Surgeon-Captain E. Downes resigns his commission. Dated May 20th, 1903. 4th West Riding of Yorkshire: Surgeon-Lieutenant P. E. Barber to be Surgeon-Captain. Dated April 25th, 1903.

Royal Engineers (Volunteers): 2nd Cheshire (Railway: Surgeon-Lieutenant E. Gray to be Surgeon-Captain. Dated May 27th, 1903.

Rifle: The Queen's Rifle Volunteer Brigade the Royal Scots (Lothian Regiment): Captain J. H. A. Laing resigns his commission and is appointed Surgeon-Captain, with precedence next above Surgeon-Captain J. A. Clark (dated August 29th, 1894); Surgeon-Lieutenant S. Hillier to be Surgeon-Captain (dated May 20th, 1903). 3rd Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Lieutenant J. P. Pendlebury resigns his commission. Dated May 27th, 1903. 3rd Volunteer Battalion the Lincolnshire Regiment: Surgeon-Lieutenant J. Bruce to be Surgeon-Captain. Dated April 25th, 1903.

INFECTED ARMY BLANKETS.

The report that a large quantity of soiled and infected army blankets had been brought from South Africa to this country and widely distributed and that an outbreak of enteric fever on board the reformatory ship *Cornwall* had been directly traceable to this cause was well calculated to give rise to the consternation with which the news was received. It certainly seems inconceivable that such an occurrence could have taken place, but the facts appear to leave no doubt on the subject. It calls for very searching investigation, for it is clear that there have been very reprehensible negligence and blundering somewhere Consequent upon the highly commendable action taken by the port sanitary officer of the corporation of the City of London in connexion with the outbreak on the training ship lying off Purfleet, the Government and sanitary authorities were promptly informed with a view to the necessary measures being taken The subject has excited great attention not unmixed with a natural feeling of indignation Both Mr Long and Mr Brodrick have made statements in Parliament in regard to it and have promised full inquiry In the face of what the War Minister said as to the existing regulations about infected bedding and materials, supplemented by the special orders issued to South Africa in regard to this matter—to say nothing of what is, or should be, common knowledge in this respect—there seems to have been an inexplicable amount of gross negligence and disregard of ordinary precautions for which somebody should be held responsible Who was it that ordered the sale of these blankets ?

Correspondence.

"Audi alteram partem."

ACUTE EPENDYMITIS

To the Editors of THE LANCET

SIRS —Having read the interesting paper by Dr J A. Coutts on Acute Ependymitis in an Infant in THE LANCET of April 25th, p 1163, it has occurred to me that brief notes of a case somewhat similar in character may be of value The case was briefly as follows A child, aged three years, was admitted into the Bristol Royal Infirmary under the care of Dr J E Shaw, with a history of having been attacked the same evening with severe vomiting On admission the child was cyanosed, the respirations were 70 the pulse was 172 to the minute and the temperature was 104° F On the following day there were twitchings of the right arm, internal strabismus of the right eye developed, and double optic neuritis was found to be present. The child died the same evening At the necropsy the brain externally appeared to be perfectly healthy and no trace of exudation could be seen over the vertex, at the base, in the Sylvian fissures, or elsewhere On cutting across the cerebral hemispheres however, the walls of the lateral ventricles were seen to be in the diffluent condition not uncommonly present in meningitis The only firm portion of the walls of these cavities, as is so commonly the case, was the basal ganglia In spite of this condition of the walls of the ventricles the choroid plexuses and velum interpositum to the naked eye presented *nothing abnormal* and *the ventricular fluid* was only slightly turbid Dr J O Symes took cultures from the fluid of the lateral ventricles and *found Friedlander's diplobacillus* Portions of the basal ganglia were taken for microscopic examination, but the sections were not cut by myself, and unfortunately the ependyma became detached and lost before the sections were made In spite of the softened character of the greater part of the walls of the lateral ventricles microscopical examination of the basal ganglia showed nothing especially noteworthy It should be added that the posterior half of the upper lobe of the right lung showed consolidation of typical lobar type The same bacillus was obtained from the consolidated lung as *from the fluid in the cerebral ventricles* *The course of* this case was very much more rapid than the case of Dr Coutts but resembled it in the sudden onset in which vomiting was a marked feature and in the presence of convergent strabismus

I am, Sirs, yours faithfully,

Clifton, May 18th 1903 THEODORE FISHER

SOUTH AFRICAN CIVIL SURGEONS' DINNER

To the Editors of THE LANCET

SIRS,—May we call attention through the columns of THE LANCET to the above dinner on June 5th at the Hotel Cecil at 7 30 P M ? Owing to the difficulty of obtaining correct addresses of many of the civil surgeons we have been unable to communicate with all those who have served in South Africa Over 800 cards of invitation have been sent out and some 50 returned as "Gone away," so we take this opportunity of endeavouring to catch the eyes of those who have *not* received *cards* Sir William Thomson, C B , will preside Guests may be invited and miniature medals and decorations will be worn

We are, Sirs, yours faithfully,

F E FREMANTLE, } Honorary Secretaries
C G WATSON, }

44 Welbeck street W May 25th 1903

THE TREATMENT OF CONICAL CORNEA

To the Editors of THE LANCET

SIRS,—May I be allowed to thank Sir Anderson Critchett for his letter which appears in THE LANCET of May 23rd, p 1477, in which he unreservedly admits the claim I made in my former letter on the above subject? I should also like to say as regards his method of "two distinct zones" that I shall certainly be disposed to give it a trial when opportunity arises in a suitable case I must add, however, that later experience has tended to show me that operation can be avoided in many cases by a suitable pair of glasses combined with general treatment

I am, Sirs, yours faithfully,

Liverpool, May 25th 1903 RICHARD WILLIAMS

ASEPTIC AND ANTISEPTIC SURGERY.

To the Editors of THE LANCET

SIRS,—In THE LANCET of March 21st, p 837, is a letter by Mr A. Webb Jones commenting on an address by Mr W Watson Cheyne on Aseptic and Antiseptic Surgery in which Mr Cheyne says that one trained solely in aseptic methods is less liable to adapt himself to his surroundings once he has to practise surgery far from the polished walls of a modern operating theatre My experience has been of a similar kind to that of Mr Jones I have been engaged in operative work in the West Indies for the past *eight years, and my results, especially in abdominal surgery*, have been very encouraging I am impressed that it is not inability in adapting oneself to the surroundings, but the blame attached to surroundings is due to the recklessness of the ordinary general practitioner in attempting surgery and instead of attributing the bad results to lack of operative skill and incorrectness in surgical diagnosis and surgical tecl [illegible] &c

I [illegible] I have obtained that the [illegible] ith the results of the operation Of course an operator always tries to obtain the best hygienic surroundings possible Two of my recent cases go to prove what I say about surroundings The first case was that of a woman, aged 65 years, the diagnosis being malignant disease of the cervix uteri The patient resides in a small house in a densely populated village and to improve matters a cooper's shop adjoins the yard of the house On March 5th, 1903, I removed the uterus, both of the ovaries, tubes, &c., and the upper part of the vagina by the abdominal route The patient has done well, the wound healing by first intention and the stitches were removed on the tenth day The second case was that of a man, aged 40 years, the subject of appendicitis, who resides in another densely populated village. I operated upon him on April 5th, 1903, at his own house—a small room 12 feet by eight feet The appendix *vermiform* was bent upon itself and very *adherent* , the tip of the appendix was alongside the cæcal origin of the appendix. This case did well ; all the stitches were removed on the seventh day the wound healing by first intention The patient is up and about

I have had several such cases and I feel the more convinced that it is the man and his methods that succeed in surgery and the surroundings should never be blamed All of my cases are prepared for operation as though they were in the most up to date equipped hospital My instruments are boiled in soda and carbolic solution for one hour The dressings, gauzes, aprons, towels &c., are sterilised in a Schimmelbusch *steriliser* under a steam pressure of ten pounds for one hour, [illegible]

no part in the surgical operation, provided the methods are perfect. The windows are all open during the operation and I have never had any sepsis that I could attribute to the surroundings. I see to the preparing of the patient as to the cleaning of the site for operation and the carbolic compress. I sterilise my own gut, instruments, dressing, &c., and last, but not least, I always dress my cases myself and check the temperature taken by the nurse, and I feel always quite convinced that should anything occur after I have sealed up an abdomen such as sepsis, it would have taken place in the most up-to-date glazed-tiled hospital ward.

I am, Sirs, yours faithfully,
FREDERICK DEANE, F.R C.S. Edin.

THE SURGEON AND THE CARPENTER.

To the Editors of THE LANCET.

SIRS,—I for one admire that surgeon who, according to Sir W. H. Bennett, "considers himself nothing much better than a good carpenter." For I understand him to signify, in slightly allegorical terms, that his chief concern is towards the attainment of perfect manual dexterity and a perfect knowledge of normal and pathological anatomy. He does not, as I interpret, aspire to proficiency in the understanding of the human organism as a whole, but rather, when he operates, is content to regard his task as a carpenter might, who cuts and planes and drives his nails and screws all with studied indifference to the feelings of surrounding structures, except perhaps—and even these are, I understand, not invariably exempt—when they happen to be gas-pipes or water-pipes or telephone wires. It is the success of the operation and not the general welfare of the patient's whole body that is paramount to him. And I, for my part, admire the surgeon who can thus concentrate his mind upon the part and faithfully shut out any disturbing considerations concerning the result to the whole.

But, Sirs, the whole—the coöperative body and spirit—must surely need an advocate, and some proved and disinterested advocate too, skilled in the consideration of the dangers and drawbacks as well as of the necessities and advisability of recourse to human carpentry. If the surgeon is to be "nothing much better than a good carpenter," surely, at any rate where main timbers may by any possibility be involved, some architect or overseer is needful, someone specially skilled in assessing the damages and estimating the practicability and expenses of the repairs. For how often, in his anxiety to make his mark, is the present-day surgeon led to interfere with parts that do not in reality seriously inconvenience the whole? How often are parts rudely interfered with when they are no more than temporarily deranged and would spontaneously return to their normal conditions if only granted a little grace? How often when the arms of death have already unerringly embraced the whole will the surgeon, with worse than blind enthusiasm, embark in extensive predoomed endeavours to rescue the part? The temper of the surgeon of the day appears to be towards challenging the right of physicians to criticise the results of surgery and indignantly resenting any interference at their hands or from anyone—and I fancy Sir W. H. Bennett, surgeon though he be, will not in all quarters escape condemnation for what he has ventured to tell us—who pleads for rational moderation in the matter of operations.

So it is that we come to read—and this has become a favourite topic with the lay press—of all the enormous increase of operative procedures. Sir W. H. Bennett's experience, from which he so admirably quotes, has probably been largely gleaned in the metropolis. Had he the benefit of having watched the careers of operating general practitioners in the provinces I have no doubt that his remarks would have been even more severe than they were. There are not a few surgeons among us who appear never to emerge from Sir W. H. Bennett's "first stage," but who as an alternative for the later ones become very proficient in the art of extricating themselves from difficult positions as they arise. And at present they undoubtedly have the public on their side and in a mood which condones failure with extraordinary readiness.

But it is my serious belief that Sir W. H. Bennett will be proved by time to be a true prophet when he says that "ere many decades have passed away the operating surgeon will be a far less imposing figure than he now is," and I venture in addition this warning, that popular estimation is a treacherous helm and one that is apt to cause its ship to veer widely. And as the public to-day undoubtedly suffers from an excessive antipathy to venesection, so the day may come when we shall see the present excess of all-round surgical interference replaced by an undue and indiscriminate distrust of it, bred of retaliation in the minds of a disabused laity.

I am, Sirs, yours faithfully,
EDGAR TREVITHICK, M.D. Cantab.
Cheltenham, May 26th, 1903.

ASPECTS OF LIFE ASSURANCE.

To the Editors of THE LANCET.

SIRS,—As one much interested in life assurance I venture to answer the letter of "N. M. R" which appeared in THE LANCET of May 23rd, p. 1478 In the first place I believe that I am correct in stating that it is the custom of all offices in cases of suicide to pay if the policy has been assigned; secondly, many offices have a clause in the policy which makes it indisputable after the payment of a certain number of premiums, usually five; and lastly I doubt whether any office would dispute payment in the event of death by suicide, especially if there were any medical evidence available to show that the deceased was mentally in a condition of unstable equilibrium at the time that the act was committed.

As to whether it is desirable that payment should be made in the event of suicide, assigned policies alone excepted, is another question It may be argued with much force that the fear of leaving his family unprovided for may have a deterrent effect on the would-be suicide; remove this fear by the knowledge that his assurance money will be available for the support of his family and you do away with the last check on his rash deed. Definite information as to the custom of the various offices in respect to claims due to suicide is much to be desired.

I am, Sirs, yours faithfully,
Wimpole-street, May 25th, 1903 F. DE HAVILLAND HALL

To the Editors of THE LANCET.

SIRS,—The cases of suicide referred to by your correspondent "N. M. R." in THE LANCET of May 23rd, p. 1478, would be fully secured by the conditions of insurance which hold at the office with which I am connected and I believe at most of the first-class offices—viz, (1) that after the completion of a full year's insurance death from suicide is accepted as a claim as from any other cause; and (2) the cases in which a policy is taken as security in the course of business death by suicide at any time does not affect the validity of insurance.

I am, Sirs, yours faithfully,
May 22nd, 1903. C. M. G.

A QUERY IN EMBRYOLOGY.

To the Editors of THE LANCET.

SIRS,—I was particularly interested in "Oxon's" letter in THE LANCET of May 16th as I witnessed an almost identical experience in the canine race which may be worth recording.

The facts relate to kangaroo hounds, a breed of dogs well known in Australia; the puppies exist, as a rule, more on account of the deeds of their parents than because of any purity of descent, consequently the characteristics of the hounds vary in different districts, but generally they partake more or less of those of a greyhound, and this applies particularly to the two hounds of which I write. I have no record of dates and the occurrence took place at least seven years ago, but my memory is quite clear as to the main facts. On a certain Friday I took a white and blue bitch to be lined by a brindled dog and they were shut up together from the Friday night till the following Monday afternoon, the owner of the dog being quite clear that service was duly performed more than once and for the first time on the Friday evening. I removed the bitch on the Monday and on the way home met a friend who was followed in the distance by a sheep dog; my bitch, on ahead, met the sheep dog and though I galloped up was too late, to prevent connexion. In due time (though I did not note the exact number of days) a batch of seven puppies arrived and they were a very disappointing lot. However, my men insisted that mixed litters did occur (? do they), and we picked out the three most likely-looking pups, two of which lived to maturity and proved to be undoubtedly sheep dog crosses; they had semi-rough coats with a short feather on the tail and barked in the chase. I know that the brindled kangaroo dog was potent because he was not only the father of many dogs in the district but two of my bitches had pups to him the following year. The kangaroo dog was an oldish dog at the time, probably six or seven years old; the sheep dog, on the other hand, was between eighteen months and two years old. The bitch was about three years old. The questions arising are :—1. How long will spermatozoa live in utero? 2 Were the ova fertilised before connexion with the sheep dog? 3 Are spermatozoa from an oldish or debilitated animal so much less active than those from a younger one that they take several days to fertilise an ovum? 4. Can the male elements be replaced in a fertilised ovum several days after fertilisation? I do not believe in maternal impression and it certainly would not account for the barking in chase.

I am, Sirs, yours faithfully,

B So.

May 19th, 1903.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Unhealthy Military Stations.—The Plague Epidemic.—The Excessive Heat.—The Continued Famine.—The Improvement Scheme for Calcutta

FROM time to time various military stations in India have been reported upon as exceptionally unhealthy and attention has been drawn to the great loss of service as well as of lives entailed thereby. There is less excuse in these days of railways and rapid transit for their maintenance and so-called military considerations have not now the same weight that they formerly had. I would draw further notice to the excessive sickness at Fort Dufferin from malaria, to the high mortality from dysentery in Barrackpore, and to the high rates for the constantly sick in Delhi, Ferozepore, Mean Meer, Nasirabad, Jhansi, Jubbulpore, and Pallavaram. The chief cause of sickness in nearly all these places is malaria, but the death-rate for all causes in some of them is enormous. There is a rumour that Barrackpore is to be given up as a military station and the troops transferred to Dum-Dum.

The plague returns issued from Simla show a reduction in the number of deaths as compared with the previous week, but the total is still very high, being 28,146. The figures returned by the various localities are as follows Punjab, 17,068 deaths; United Provinces, 3139; Bombay Presidency, 3357; Bengal, 1863; Bombay city, 1146; Karachi, 197; Madras Presidency, 42; Calcutta, 434; Central Provinces, 221; and Hyderabad State, 423. The above figures show that the disease is raging with great virulence in Karachi and in Bombay city, but later returns show a marked improvement in Calcutta

During the past fortnight the heat in many parts of India has been intense. In Calcutta the shade thermometer recorded 109° F., in Jessore 108°, in Midnapore 111°, and in Berhampore 114°. There are still people who believe in the deterrent effect of a high atmospheric temperature upon the spread of plague notwithstanding that the disease has developed in Karachi, the Punjab, and Calcutta almost every year with the hot dry weather of the months of March, April, and May

Famine is still existent in India. In the Central Provinces the numbers under relief are increasing and the total is now 62,051, of whom 45,559 are on relief works.

The great improvement scheme for Calcutta is threatened with comparative uselessness, as beyond the making of new roads there is no provision for other improvements. All available means are likely to be swallowed up on this limited programme and the bustees and by-lanes and gullies, surface drainage, and privies will be left to be dealt with in the ordinary course. The great cry now is that no provision is being made for the large population displaced by the activities of the plague department. There is the same wail in Bombay. Thousands have been rendered homeless and the result has been that the neighbouring quarters to those demolished have become still more overcrowded. It may be said to be an aphorism of modern sanitation as applied to great cities that construction must go hand-in-hand with destruction. An attempt has been made to carry this out in Bombay but in a degree wholly incommensurate with the population displaced In Calcutta nothing has been done at all.

May 9th.

THE SECOND INTERNATIONAL CONGRESS OF THE MEDICAL PRESS.

(FROM OUR SPECIAL CORRESPONDENT.)

THE SECOND DAY.

Madrid, May 10th.

ON the Wednesday (April 22nd) morning it was thought that we should reach the real business that had brought us together—namely, the vote upon, and the definite acceptance of, the statutes of the International Association of the Medical Press A strong desire was, however, expressed to obtain some manifestation of opinion in regard to the questions discussed the previous day and this in spite of the fact that the Congress was not in a position to vote, for it had not as yet decided on the method of voting. But it was nevertheless maintained that it would be time enough to discuss the constitution of the association in the afternoon while the Congress might express its opinion in the morning on some of the general questions. Such expression of opinion would not have any binding effect, it would not be a "legislative" act but merely a manifestation of opinion of a platonic description. This seemed to be somewhat illogical, for if the Congress had the power to vote a constitution, which is certainly a serious and anything but a platonic matter, its other resolutions should have equal force. But then the constitution by establishing the vote by nationalities would certainly render the vote of the congress far more representative than by the mere raising of hands Therefore the general discussion was resumed and Dr. BLONDEL proposed that the Congress should not consider as medical journals publications that only reported the meetings of societies. Dr. VIDAL agreed, saying that in the absence of some such rule a phonograph would suffice and the owner of the phonograph would call himself a journalist

Dr. ASCOLI (Italy), like Dr. POSNER (Berlin), thought that such reports of meetings of societies were useful but to constitute a journal other matter should be published. Even if medical men grouped themselves together so as to produce a journal collectively, and if this, in the course of evolution, tended to benefit science, they would not complain even though it were qualified as medical socialism

Dr. FRANK POPE (Leicester) asked for a more distinct definition, otherwise such a resolution might be taken to exclude the *British Medical Journal*. This question caused some amusement and elicited complimentary remarks acknowledging that the *British Medical Journal* was a journal and contained all that a journal was expected to contain, apart from being the organ of the British Medical Association Dr. Pope then urged that each section should be left to decide what might legitimately be considered as a journal.

Dr. SUAREZ DE MENDOZA (Paris) inquired what was to be done with the bulletin of the French Academy of Medicine, but in spite of this question a motion to the effect that periodicals which only published the record of the proceedings of societies should not be considered as journals was unanimously approved

The Congress now discussed the question of gratuitous papers Some French firms publish, it appears, what purport to be medical journals in the Spanish language and send these papers gratuitously to Spanish medical men. Of course, the object is to promote the sale in Spain of French proprietary drugs and remedies.

Dr. POSNER said that this was a serious matter, for undoubtedly some of these papers were very well written and the writers were well paid for their articles. In Germany these papers went a step further. They assumed the cloak of philanthropy and collected and distributed funds for the relief of the widows and children of medical men. These papers circulated all over Germany. There was one which, while calling itself a medical journal, devoted most of its pages to questions concerning dental instruments.

Dr. MENDOZA said that gratuitous papers could only be issued for the sake of selling drugs or instruments, therefore they were not journals but *trade circulars* Nevertheless, they contained good matter—notably the publication issued by Messrs. Faillière of Paris.

Dr. ULECIA Y CARDONA, while declaring that the evil did not exist in Spain, admitted that it was likely to spread. They might carry condemnatory resolutions but as soon as their opinions were known the dealers and manufacturers would so disguise themselves as to escape censure. They could secure the services of medical men and pay them well. Could they boycott medical men who accepted such payment and were there not many medical men who would set such ostracism at defiance?

Dr. Pope remarked that this sort of thing also existed in England but that the greater number of such publications were sent across the Atlantic or to Germany. There were papers that were gratuitous or nearly so, but the *bonâ-fide* nature of a journal could only be judged on the spot. The national associations must exclude unworthy prints and the action of the national associations must be supported and sustained by the International Association.

Dr. Totimo divided the papers into two groups, those published to diffuse science and those which only utilised science as a means of selling goods. The first category alone should be admitted.

Here Mr. Adolphe Smith intervened in the discussion to remind the Congress that at the Monaco Conference, after careful consideration, it was decided that the association was to be representative exclusively of the scientific and literary side of journalism. The commercial side was absolutely excluded. This rule had been strictly observed by the Association of the British Medical Press. Its members were admitted as editors or contributors to medical journals and not as proprietors or business managers of those papers. The most effective means of dealing with the evils mentioned was to maintain a high standard of journalism and if this was properly done the sham journals would soon disappear.

Dr. Totedo agreed and said that all papers were dual concerns. There were the scientific side and the business side, but the association was created solely for the scientific side. He did not think that medical men should take in papers published by manufacturers and such papers should not be admitted in the society.

Dr. Calatraveno urged that no industrial paper should be admitted, that no exchange with them should be made, and that medical men who wrote for them should not be considered as fellow professionals.

Dr. Mendoza rose to modify the very condemnatory tone that was being adopted and recalled a Spanish proverb. If a poor man took too much alcohol everyone said he was drunk, but if the man was rich then it was said that he was only a little cheerful. Where was the line to be drawn? Nearly all the papers published advertisements if they could get them. A member of the French Medical Press Association wrote for the paper published by Messrs. Faillière and they were very good articles. Should they not recognise good scientific material wherever they found it without looking too closely into the sources whence the money was derived to pay for its publication?

At this stage the discussion dropped and the Congress adjourned for lunch.

On meeting again the Congress at last grappled with the real business, and as now we should have to vote, and to vote seriously, we must begin at the end by taking Article XII. first, as this defined the method of voting. Dr. Cortezo, who occupied the chair, called upon Mr. Adolphe Smith to explain. There was no difficulty in demonstrating that the vote must be by nationality and also that some difference must be made between nationalities. But it was proposed to add a definition of small nationalities to the Monaco text, which now ran thus: "At the general assemblies [congresses] the votes will be by nationality."

> So as to give a voice to the minority within each nationality five votes shall be given to each large nationality and three votes to the others. For the present those shall be considered as large nationalities whose populations exceed 10,000,000.

What was not so clearly understood was the manner of recording the vote. Mr. Adolphe Smith endeavoured to explain that it was merely a matter of simple arithmetic. Every nationality must appoint its teller and the vote must be put separately to each nationality, the teller apportioning the vote of his nation according to the division of opinion that might occur; thus, if a small nationality had 12 delegates present and eight voted for and four against a motion, the three votes of that nationality would be recorded as two for and one against. If a delegation could not be divided exactly by its three or five votes the nearest possible approximation must be given. After a few questions had been put and answered the motion as given above was carried unanimously, and thus this really important innovation in the manner of organising international congresses which had been approved at the Monaco Conference was now definitely confirmed and sanctioned by the Madrid Congress. The other rules relating to the general assemblies of congresses of the International Association of the Medical Press were carried with hardly any alteration whatsoever.

Article I., on which it had been anticipated that an amendment would be moved, was now taken in hand. It was explained that in the French national association only journals were represented, that in Germany one journal sent several representatives, and that in Spain journals of kindred professions were admitted. As customs differed so widely it was necessary to leave each country to decide for itself as to who should be admitted, but the question was now raised. The amendment proposed by Dr. Mendoza was that the individual should have the right to appeal to the Congress as a whole against the decision of his own nationality. This demand was based on the belief that in France persons had been condemned without being heard or possessing any sort of right of appeal.

Dr. Dejace (Belgium) maintained that the Congress could not do better than, or as well as, the nationality concerned, where alone the necessary information could be obtained.

Dr. Blondel followed, giving chapter and verse concerning the incident alluded to as occurring in France. He showed that there had been an investigation and that there was a right of appeal and that full reparation had been made for whatever error had been committed. In the face of this announcement Dr. Mendoza withdrew his amendment and Article I. of the statutes was carried unanimously. The International Association of the Medical Press, therefore, is to consist of journals or journalists approved of, or elected by, their respective national associations of the medical press. Article II., that copyright is to be respected and an international subscription paid, was carried, but Paragraph 1 of Article III. gave rise to a very lengthy discussion. The article was carried unanimously when the disputed sentence was removed so as to be put as a separate article and question. The question was in regard to clinical or university lectures, whether the professor could retain the copyright of the same. In Spain the law was in favour of the professor, but it was against him in France.

Dr. Posner said that there was an abuse. In Austria papers were published and kept alive by students who went and took notes when some celebrity delivered a lecture and then published these notes in such a manner that it seemed as if the professor in question had written a special article for the paper. The professor, as a matter of fact, knew nothing about it, and such trading on a well-known name should not be countenanced.

Dr. Pope said that lectures delivered in great faculties were taken down in shorthand and published. It was the business of a journal to do this well and promptly, as a matter of reporting.

Dr. Dejace urged that the professors were paid by the Government and what they said was said for the public. When necessary the journalist paid to enter and he had a right to take notes and to do what he chose with what he heard. The association which they were founding was an association of journals and journalists, not of professors and lecturers.

Dr. Posner objected that in jurisprudence the property of the lecturer was respected.

Dr. Cortezo, from the chair, said that they had voted against such proprietary rights at Monaco. They were here creating frontiers and the press would find it very difficult to feed itself. Medicine had its humanitarian side and all that tended to spread useful knowledge should be encouraged.

After some further remarks from one or two delegates the matter was put to the vote and there now occurred a good opportunity of testing the new system of voting, because it so happened that one nation, France, was very divided in its opinions on the question. The rule proposed was:

> That lectures cannot be published without the sanction of the professors.

The vote was as follows: Germany, 5 for; Belgium, 3 against. Now came the turn of France and the French vote was 3 for and 2 against. Then followed Spain, 5 against; England, with only two delegates present, voted 5 against—thus the two British votes were as influential as that of the 50 or so Spanish delegates who were attending the Congress. Thus also neither Great Britain nor any other nation was placed at a disadvantage by the fact that, meeting in Madrid, there were far more Spanish delegates present than delegates from any other country. Italy voted 5 for, Argentina and Norway 3 each for, and Venezuela 3 against. The resolution was thus carried by 19 votes against 18. The full details of this division deserve to be recorded, so that the system may be understood and a precedent created. All the other rules, with but some slight verbal alterations, were now adopted. Nevertheless, it was thought necessary to meet again on the following morning. It was the committee rather than the Congress that had still some important work to do. Therefore on Thursday we were back once more at the Central University and the international committee met in a private room. The question arose as to whether the system of the nationality vote was to apply to the committee meetings. In answer Mr. Adolphe Smith remarked that the committee was an executive and not a legislative body. It had to carry out decisions adopted in as practical a manner as possible and was governed exclusively by considerations of expediency, the questions of principle having been established by the constituency, that is by the Congress. Therefore, votes in committee should be by show of hands. The first matter to decide was the election of the officers. After some discussion but by a huge majority Dr. Cortezo was elected as president. We had all acquired considerable experience of Dr. Cortezo's tact and unfailing courtesy, as he had presided on behalf of Spain at all the sittings of the Congress. Dr. Posner, Dr. Dawson Williams, and Dr. Ascoli were elected as the three vice-presidents. Therefore there is a Spanish president with German, English, and Italian vice-presidents. France, in the person of Dr. Blondel, is represented in the post of general secretary, and Belgium retains Dr. Pechère as assistant secretary and treasurer. It was then decided that at least the International Committee should meet at Brussels immediately before the International Congress of Hygiene which will assemble in that town on Sept. 3rd this year.

We now proceeded to the grand hall, the *paraninfo*, of the University, and there Dr. BLONDEL read a paper on the Establishment of an International Information Bureau. No paper, he maintained, could have correspondents in all parts of the world, and just as the political daily papers had to subscribe to press agencies such as Reuter's so might a similar agency be organised for the benefit—the exclusive benefit—of medical journals belonging to the International Associational of the Medical Press and this might prove an inducement to papers to join that association. He thought that a central bureau should be created under the patronage of the association to which all the papers would send summaries of their more important publications which would be distributed by means of the agency.

This explanation led to the asking of a few questions and the expressing of some doubts, and then Dr. ELÉZIA, who had been one of the delegates at the Monaco conference, rose and proposed that the association now definitely constituted should send a telegram to the Prince of Monaco thanking him once more for his hospitality and help during the earlier stages of the endeavour at organisation.

This was carried unanimously.

The names of the officers of the association were now read out amid great applause.

Dr. BLONDEL said a few words to thank the Spanish committee and its general secretary, Dr. Larra, and

Dr. CORTEZO gracefully alluded to his sorrow that the moment of parting had arrived. He did not know how to express his gratitude for the honour that had been conferred on him; he accepted the presidency, not as a personal matter, but in the name of Spain and as an honour conferred on his country.

The Congress having completed its task rose and was dissolved, the members hurrying to their respective quarters to prepare for the inaugural ceremony of the other Congress, the Fourteenth International Congress of Medicine, which was to be held that same afternoon.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday Fund.

NINE years ago the managers of this Fund were able to open a convalescent home for women at Llandudno in part of an old house called Marle Hall. This home when opened was very inferior in size to the neighbouring house called Tyn-y-Coed which was intended for male occupants. Marle Hall was originally a monastery which was burnt out and restored in the sixteenth century and again destroyed by fire in the eighteenth century. It remained a ruin for 100 years when one wing was rebuilt and occupied for some time by members of a well-known Staffordshire family. Nine years ago the Hospital Saturday Fund acquired this wing for the purposes above mentioned. The accommodation only permitted of the keeping up of 22 beds, a number soon found to be altogether inadequate; consequently a second house, also for the use of women, called Yr Erw, was rented, but even this did not meet the necessities of the case. It was therefore decided to purchase and to restore Marle Hall and this has now been done at a total expense of £16,000. The result is said to be architecturally satisfactory and the building will accommodate 85 convalescent women. Of the sum of money expended £5000 were to hand from accumulations of the fund and £1500 have since been given. The total number of women who have passed through the two homes mentioned above since they were opened has been 6620. The number of men who have passed through Tyn-y-Coed has been 8262, whilst 1193 children have been accommodated at Bryn Marle and at the Red House, Great Barr. Thus 16,075 convalescents have been occupants of the various homes maintained by the Fund since this part of the work was undertaken. At the opening of Marle Hall, which took place a few days ago, Alderman Cook, the chairman of the Fund, presided, and the Lord Mayor and Lady Mayoress of Birmingham were amongst those present, the latter performing the ceremony of opening the home. The committee anticipates that it will take several years to pay off the debt upon the buildings unless some large donations are made for that purpose or the subscriptions of the members of the Fund are increased for a time. The maintenance of the enlarged homes will also, of course, be an increased burden upon the Fund and it is calculated that at least £20,000 per annum must be raised in order to carry on all the work which is now being done

Walsall Dispensary.

A provident dispensary has now been formed in Walsall in order to take the place of the clubs which have recently been disbanded and the rules under which it will work have been made public. This dispensary is intended to provide medical attendance and medicine for persons unable to pay ordinary medical fees. It is to include, in the first instance, all the medical men now resident in the district who can be persuaded to join it. As new-comers take up their residence with the intention of practising they are to be invited to join and are to be furnished with a copy of the rules by the secretary. The medical officers are to be of two kinds: active, who treat the patients of the dispensary; and honorary, who do not. Both classes will be entitled to attend the meetings of the dispensary and if elected to hold any office in it. Persons wishing to join as patients are to apply in the first instance to the secretary at the office and he is to provide them with a card to take to such medical officer as they may select. After the necessary expenses of the dispensary have been paid each quarter the remainder of the money is to be divided amongst the active medical officers in proportion to the number of patients on their respective lists. The expenses are to be apportioned in the same manner and the committee is to decide as to the eligibility for membership and the continuance of the same of patients. In the case of a patient apparently too well off to belong to the dispensary, the committee, on having the matter brought to its notice, is to inquire into it and to decide what course is to be adopted. When a medical man joins the dispensary he will be required to sign a declaration to the effect (1) that he will not take any contract patients at a lower rate than that paid to the dispensary, except members of existing friendly societies; (2) that he will not advertise for patients directly or indirectly; (3) that he will obey the rules of the dispensary and do nothing contrary to its welfare; and (4) that he will not meet professionally or in consultation non-conforming medical men. Power is given to the committee to call upon any medical officer who does not conform to the engagement which he has entered upon [illegible] in the event of his refusing to expel him. In [illegible] staff his [illegible]

Club Statistics.

A very interesting and valuable report on club statistics for the year 1902 has been prepared by the executive committee of the Birmingham and District General Medical

Practitioners' Union and published in its organ, the *Midland Medical Journal.* The statistics which have been tabulated relate to 34 clubs and the collected figures are sufficient to show the average rate of payment by local clubs for sick attendance. In the first place, the committee endeavoured to ascertain what was the average rate charged in private practice by general practitioners in the district for medical attendance on the working-classes who chiefly form the clubs which were the subject of inquiry. It appears that the average fees charged were 2*s.* 6*d.* for a visit, with medicine included, if necessary, and 1*s.* 6*d.* for a consultation with or without medicine, while "repeat" medicines were charged at a like price. It was then desired to ascertain how nearly the payments made by the sick clubs approximated to this standard, and after various methods of arriving at this conclusion had been tried it was finally decided to calculate how much the receipts would have been had the club patients been private patients. Taking all figures sent in it was found that in 1902, in 34 clubs there were 3063 visits and 13,042 consultations and medicine, remunerated by a sum of £786 19*s.* 7*d.*, whereas the sum received should have been £1361 0*s.* 6*d.*, a percentage of 57. Some of the clubs, however, consist mainly of old men and seem to be retained by their medical officers out of charity. When these are excluded from the calculation it is found that amongst the selected clubs there were 2108 visits and 9401 consultations, and that the remuneration was £627 10*s.* 9*d.* The remuneration on the lines indicated above should have been £968 11*s.* 6*d.*, so that the medical officers should have received half as much again as they actually did receive. On the sickness rate of 1902, which was rather lower than the average, a slight margin in favour of the medical man would have been left had each member paid 6*s.* per annum or 1½*d.* per week. Summing up the matter it may be said that the average rate paid per head of all the clubs of which information was to hand is very nearly 3*s.* 4*d.* on upwards of 3400 male adults and the average remuneration is 65 per cent. of the amount calculated above to be reasonable for a year which had less than the average sickness. It is pointed out that the figures only apply to a large city like Birmingham where the hospital facilities are great and where many of the most serious medical and surgical cases are sent, as a routine practice, to receive gratuitous treatment at these institutions. The multiplicity of these, while injuring the practitioner in his private practice, undoubtedly relieves the man in club practice of much onerous work, so that the rate of pay which would be equitable in a large city is by no means so great as it should be in small towns and in country practices.

May 26th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Small-pox in Liverpool: the Outbreak steadily declining.

DR. E. W. HOPE, the medical officer of health, made the satisfactory statement at the meeting of the health committee on May 21st that the epidemic of small-pox in Liverpool was steadily declining, but that he had no intention of relaxing any of the precautions hitherto adopted and especially that of vaccination and revaccination. It would be interesting to consider what had been the incidence of the disease on young children under five years of age. From the returns it appeared that about 7 per cent. of the children in Liverpool had escaped vaccination during the last six years, but he would take a liberal estimate and say 10 per cent., leaving 90 per cent. vaccinated. If the incidence of the disease were the same on the vaccinated and the unvaccinated, as the anti-vaccinationists insisted, the expectation would be that 90 per cent. of the cases among these young children would be among the vaccinated and 10 per cent. among the unvaccinated. The statistics, however, for the last six months showed that 71 children in Liverpool below the age of five years were attacked with small-pox and of these 66 were unvaccinated, while the remaining five had been vaccinated very imperfectly. These facts were very striking, but the most important point was that in the case of each of the vaccinated children the illness was very mild and each child soon recovered. In each of the 66 unvaccinated cases, however, the illness was very severe and 30 per cent. of the children died. During the last five years the rate of mortality from small-pox among the previously vaccinated was 2 per cent. of all ages, while among those not vaccinated it was 37 per cent. Within the last 18 months an enormous number of people in Liverpool, over 80,000, had been revaccinated, and from among them not a single case of small-pox had been admitted to hospital. Though the disease was now declining very fast there might be fresh importations and it would not be surprising if the decline were interrupted; therefore, precautions must be continued and revaccination should be performed wherever necessary. The weekly statistics showed that during the past week there had been six deaths from small-pox; 37 cases were reported, against 63 the week before, while there were 253 cases in hospital. The following record will show the incidence of the disease during the last three months: During the week ending March 7th, 88 cases were reported; March 14th, 84; March 21st, 85; March 28th, 67; April 4th, 62; April 11th, 66; April 18th, 94; April 25th, 69; May 2nd, 69; May 9th, 62; May 16th, 63; and May 23rd, 37 cases. The number of cases in hospital on March 19th was 335, as compared with 253 last week. These figures show that the health authorities of Liverpool are dealing with the epidemic as speedily as they possibly can. It is very easy for people outside to say that there is a greater spread of small-pox at the present time than a few months ago, but such statements are looked upon with surprise and amusement by the medical profession of Liverpool, who have the fullest confidence in Dr. Hope and his assistants. Moreover, Dr. Hope has managed to cope with the disease without the smallest friction with his medical *confrères* who at all times are only too ready to afford him all the assistance in their power in the matter of notification and in advising patients to go to hospital. It is generally admitted that no greater vigilance could be exercised than by the health department of the city.

Reported Escape of Small-pox Patients from Hospital.

The town clerk of Liverpool has informed the President of the Local Government Board that he caused inquiries to be made as to the statement that five patients had escaped from the Liverpool Small-pox Hospital. He found that there was no foundation for the report that five patients had escaped. One patient managed to get out of the hospital and reached a farmhouse in the precincts of the hospital grounds, but was promptly taken back to hospital.

Liverpool University.

Among the unopposed measures which came before the Earl of Morley, the chairman of committees in the House of Lords, on May 26th was the Liverpool University Bill The object of the Bill is to separate the University College, Liverpool, from the Victoria University and to establish a Liverpool University, transferring all the property and liabilities of the College to the new university. Principal Dale of University College proved the preamble and the charter was also produced. The Earl of Morley having examined the clauses the Bill was passed and ordered to be reported for a third reading.

Liverpool School of Tropical Medicine: the Tsetse Fly Experiments in West Africa.

Dr. J. E. Dutton and Dr. Todd of the Senegambia expedition in connexion with the Liverpool School of Tropical Medicine have recently made a short visit to Bathurst, preparatory to a visit to Senegal. They have been conducting a considerable number of experiments in the colony with the tsetse fly on various animals, the results of which they are sending to Liverpool for further investigation at the Johnston Laboratory at University College.

Generous Gifts to Liverpool Hospitals.

The treasurer of the Stanley Hospital has received an anonymous gift of £1050 towards the cost of erection of the new operating theatre. Mr. Heath Harrison has also sent a donation of £250 to the funds of the David Lewis Northern Hospital. The gift comes at an opportune time, as the committee has recently had to realise securities to the amount of £500 in order to meet current expenditure.

Munificent Donation to the Crewe Cottage Memorial Hospital.

Mr. F. W. Webb, the retiring chief mechanical engineer of the London and North-Western Railway Company, has given the munificent sum of £5000 towards the endowment fund of the Crewe Cottage Memorial Hospital. The hospital owes its inception to Mr. Webb who, in conjunction with Mr.

Henry Yates Thompson of Liverpool, subscribed a large amount which made the erection of the hospital possible.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Typhus Fever in Merthyr.

THE story which Mr. D. J. Thomas, the medical officer of health of Merthyr, has to tell in his annual report of an outbreak of typhus fever which occurred in Dowlais during 1902 is not at all pleasant reading. The last occasion on which the disease appeared in the town was in 1894 and in previous years there had been outbreaks. In 1902 there were 22 cases of which eight terminated fatally. The source of infection was in many instances defined but not in all. The insanitary conditions of all the initial cases were well established. Poverty, filth, and overcrowding were present and attention had been previously drawn to the insanitary conditions of some of the houses in question. One of the affected houses was one of a row situated on the hillside with a backyard from three to five feet wide terminating in a retaining wall 20 feet high, an arrangement which favours a stagnation of the air inside the house. There were a kitchen and a scullery on the ground floor and two bedrooms above; the capacity of the two bedrooms was 1200 cubic feet and these were occupied at the time of the outbreak by husband, wife, six children, and four lodgers. Some of the men worked at night so that the beds were in constant occupation. The one remedy for such overcrowding as this, as Mr. Thomas points out, is in the establishment of properly regulated common lodging-houses. In a district of the character of Dowlais there ought not to be any difficulty in making a lodging-house self-supporting even if erected by the sanitary authority.

Bristol Port Sanitary Authority.

In their annual report upon the Bristol port sanitary district Dr. D. S. Davies and Mr. J. C. Heaven again draw attention to the urgency of requiring shipowners to rid their ships of rats. They point out that while definite precautions are universally enforced against non-living infection-carrying material such as clothes and bedding, living infection-carrying material endowed with locomotion and of [illegible] unrestricted importation. The [illegible] his report are of such general application that they may profitably be quoted: "It would result in a saving not only to the health or lives of the crew but also to the pockets of the merchants if shipowners were compelled to take simple measures of precaution, for nothing can be more wastefully expensive than an actual outbreak of plague and 'prevention in advance,' though less showy, is far more desirable than 'stamping out,' which involves the permitted introduction of disease. Since 1901 there has been a curious lull in alarms of ship-brought plague to the United Kingdom which has not had an altogether good effect, for in the absence of actual and pressing danger it is impossible to maintain the expenditure for a properly vigilant outlook and anticipatory precautions are the last matters upon which the ratepayer is willing to be liberal, so inured by long habit has he become to the belated process of 'stamping out' at great cost outbreaks which might oftentimes at much smaller outlay have been prevented."

Bristol Workhouse Infirmary.

The controversy between the Bristol board of guardians and the Local Government Board with regard to the provision of more suitable infirmary accommodation has reached a further stage. The Local Government Board has been insistent as to the urgent nece [illegible] of the existing wooden buildi [illegible] and for erecting a permanent [illegible] board of guardians described when asking for sanction to acquire it as "eminently suitable as a site for the proposed infirmary." The Bristol board now proposes to use the Eastville workhouse almost exclusively for the able-bodied and for the aged inmates who are in good health and to treat the sick and infirm at the Stapleton workhouse, adjoining which it is proposed to erect a new building to accommodate 250 patients and a separate block to be under independent management for 500 imbeciles. Upon the receipt by the Local Government Board of these proposals two of the Board's inspectors, Mr. Andrew Fuller and Mr. E. B. Wethered, together with the Board's architect, Mr. Kitchen, reported in detail upon the scheme which they do not consider to be at all satisfactory, both on account of the difficulty entailed in adapting old buildings to modern requirements and because there would be no adequate space for future extensions.

Stratton and Bude Water-supply.

On May 21st General Sir Redvers Buller formally opened the new waterworks which have been erected by the urban district council of Stratton and Bude, Cornwall. The water is collected in a reservoir which covers 70 acres, which has a capacity of about 150,000,000 gallons, and which is situated at Bradworthy about 10 miles from Bude. The water is carried along the Bude Canal, which the council has purchased for £8000, and the filtering and other arrangements are most efficiently carried out. The cost of the undertaking has been £23,000. The urban council believes that the thoroughly satisfactory water-supply now provided will assist the town in taking its proper place as a seaside and health resort

May 26th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Ulster Branch of the British Medical Association.

AT the spring meeting of the Ulster Branch of the British Medical Association held in the Medical Institute, Belfast, on May 13th, the President (Professor T. Sinclair) brought forward a motion expressing the sincere regret of the members at the death of their treasurer, Dr. George Gray, J P., of Newcastle, co. Down. This was seconded by Dr. H. O'Neill, J P., and passed. Mr. C. K. Darnell read notes of a case of Penetrating Wound of the Abdomen by the shaft of a car and showed the patient. Dr. John Campbell read a short paper on Subperitoneal Lipomata with notes of two cases. Professor J. W. Byers read a paper on the Early Treatment of Acute Puerperal Infection. In the discussion following the reading of these communications the President, Dr. J. S. Darling (Lurgan), Mr. A. B. Mitchell, Dr. Campbell, Dr. W. A. Wadsworth, Dr. R. M. Fraser, Dr. H. J. Ritchie, Dr. J. C. Martin (Portrush), Dr. W. A M'Keown, Dr. J. T. Creery (Coleraine), and Dr. W. Calwell took part. Professor Byers proposed the following motions of which he had given notice:—

1. That in the opinion of the Ulster Branch the present position of the Poor-law medical service is most unsatisfactory and calls for immediate amendment in respect to (*a*) remuneration, (*b*) annual holidays, and (*c*) superannuation.
2. That the council of the British Medical Association be requested to adopt such measures as may be considered advisable to redress as quickly as possible the grievances of the Irish poor-law medical officers.

In submitting these motions, Professor Byers referred to the grievances complained of, the results of these disabilities, the demands of the medical officers, and the methods by which these grievances could be redressed. Dr. M'Keown (Senator of the Royal University), in seconding the adoption of the motions, spoke of the importance of a firm stand being made all along the line by the medical profession on this important question. Professor J. Symington, F.R.S., in supporting the motions, said that he had advised Belfast students not to enter the service unless the disabilities complained of were removed. The motions were passed unanimously.

Belfast Maternity Hospital.

An excellent site in a thickly populated district of Belfast has been selected for the new Maternity Hospital which it is hoped will soon be erected.

Royal Medical Benevolent Fund.

From the report of the Belfast and County Antrim Branch of the Royal Medical Benevolent Fund of Ireland presented to the members at the annual meeting in the Medical Institute, Belfast, on May 15th, it appears that the gross contributions from all sources were £172 7*s.*, less expenses £11 6*s.* 9*d.*, leaving a net sum of £161 0*s.* 3*d.* in the hands of the central treasurer. This is £4 18*s.* 7*d.* less than last year, and £19 7*s* 4*d.* below 1901. Out of 198 medical men in Belfast, 153 contributed £100 10*s.* 6*d.*, but 45, or 25 per cent. of the profession, gave nothing. Of the 213 country members 43 gave £32 2*s.*, but 170 made no response to the appeal. The amount contributed by the profession in Ireland averages only about 2s. per head per annum. Officers for the ensuing year were elected, Sir W. Whitla being appointed President, and Dr. R. Purdon secretary and treasurer.

Irish Poor-law Guardians and their Medical Officers.

The conflict between the medical officers of dispensaries and Poor-law union hospitals and the new boards of guardians has recently become more urgent every week. It seems now to be approaching an acute phase. At a meeting of the Omagh board on May 22rd, Mr. George Murnaghan, M.P., in the chair, a letter was read from the Tyrone branch of the Irish Medical Association signed by the President (Dr. E. C. Thompson, M.P.), in which it was stated that the branch had unanimously resolved to adopt the rules of the association in reference to the salaries of dispensary and workhouse medical officers as well as to the sums agreed upon as payment for substitutes, &c. The letter went on to state that "the Irish Poor-law officers were determined to adopt the system by which the tenant farmers of Ireland have effected so many useful reforms—viz , combination—and they intend to vigorously enforce the by-laws of the association which will prevent them in future making a consultation or helping in any way any Poor-law medical officer or other medical practitioner who does not support this association or who fails to help them in their efforts to obtain the redress of their legitimate grievances." When the letter had been read the chairman of the meeting said: "I think that we should draw the attention of the Local Government Board to this letter and ask them if they are going to give to these men the same treatment that they gave to the tenants when they conspired to prevent men doing what they had a legitimate right to do. It is intimidation, for they threaten any doctor who does not fall in line with them." Another difficulty has recently taken place as regards this matter in the Tullamore Union in connexion with the election of a medical officer for the Killoughey dispensary district, in which tenders were invited on the same terms as heretofore—namely, £100 as dispensary officer and £20 as medical officer of health. At the last meeting of the board no application was made and the guardians were obliged to advertise a third time for candidates for the position. The chairman, Mr William Adams, J.P., said that "he did not blame the medical officers of Ireland for organising to protect their interests, but he certainly denied their right as employés to fix their own salaries. Their duties had not increased under the new Act and if they were being underpaid it was regrettable and unfortunate that they did not look for increases when the landlords were paying half the poor-rate and when recoupment in respect of such increases from Imperial sources was more favourable. Instead of that they selected a time when the ratepayers would have to bear the whole burden, and when popular local government was so keenly observed and criticised." He concluded by saying that the guardians would fight the matter to the bitter end, and from what he had heard of the letters sent to candidates by the Irish Medical Association he would state that if they came from any of the people's organisations with which he was connected there would be imprisonment for some of the members for intimidation and boycotting. The Local Government Board has written to the Downpatrick board of guardians (under date of May 21st) saying it considers the tone of Mr. Olpherts's letter[1] to the guardians as most unbecoming and stating that if a dispensary medical officer is absent from his district the guardians have a right to satisfy themselves that proper arrangements are made for the discharge of the duties during such absence, but it is only fair to Mr. Olpherts to indicate that he says that he left the district in charge of a thoroughly competent medical man and by arrangement.

Workhouse Consumptive Patients.

The Rev. Dr. Henry, Roman Catholic bishop of Down and Connor, has written to the Belfast board of guardians offering them a site at Orlands, a beautiful estate which he has purchased on Belfast Lough, free of rent, on which to erect wooden cottages or bungalows for 100 or more consumptive patients. The sisters of mercy in charge of Orlands undertake to give their own valuable assistance as well as the services of trained nurses for the relief and benefit of the patients. The bishop was thanked for his generous offer and the matter was referred to a committee of the infirmary committee.

officers to pay fines amounting to a total of 70 francs (£2 16*s.*). The medical officers, however, refused to obey this order and quitted their posts, leaving only one of their number to attend to cases of accident.

New Methods of employing Antitoxic Sera.

At a recent meeting of the Academy of Science M. Calmette gave an account of a very ingenious method of using anti-tetanic serum, the serum being dried, pulverised, and applied as a dressing to wounds which are presumably infected by tetanus. Anti-tetanic serum has hitherto not fulfilled the expectations which were hoped for from its use. Administered as a preventive it exercises a prophylactic action for some 15 days, but employed in patients already attacked by tetanus it is very uncertain in its action even though it be employed by means of the heroic method proposed by Borrell and which consists in injecting serum into the cerebral substance through an opening made by a trephine. Calmette used guinea-pigs for his experiments and infected wounds made in them with earth which was full of tetanus germs, the guinea-pigs all dying within four or six days. Other guinea-pigs, however, treated in the same way as regards infection, but whose wounds were dressed with the powdered anti-tetanic serum all lived. The dressing must be applied within six hours after the wound and if applied later the results are uncertain. This discovery should be of great interest to employers of navvies and others engaged in excavating works, among whom tetanus is frequent and whose wounds are so often infected by the earth, all the more because a serum prepared in this manner preserves its properties indefinitely and seems capable of many applications. In Indo-China, for example, some 20 per cent. of the newly-born children die from tetanus owing to infection by the umbilical cord when the dry portion falls off. M. L. Martin of the Pasteur Institute has brought forward a somewhat similar method of treatment by employing anti-diphtheritic serum as a dressing to the false membranes of diphtheria. M. Martin obtains his serum in a different way from the method of Behring and Roux, as he injects directly into the veins of the horse the microbes of diphtheria after having been heated up to 100° C. The serum [illegible]
superior to [illegible]
is applied [illegible]
causes ther [illegible]
off and the [illegible]
is thus thoroughly disinfected, and in order to render the effect more prolonged M. Martin proposes to incorporate his serum with gum so as to form a jujube which can be slowly sucked. We have here a method of applying diphtheritic serum which without dispensing with the injection of serum in definite cases of diphtheria will most likely diminish very largely both the gravity and the duration of the malady and probably, too, the method may act as a preventive in times of epidemic if applied to patients threatened with diphtheria.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Sanatoriums for Tuberculous Patients.

THE German central committee fo [illegible]
sanatoriums for tuberculous patients [illegible]
in Berlin on May 17th. About 200 members were present,
[illegible] (Secretary of State), Herr
[illegible] Professor Leube of Würzburg,
[illegible] of the Government Medical Department). Count Posadowsky, who presided, delivered an address in which he called attention to the question of the housing of the poorer classes. He said that healthy dwellings were a prime requisite in the prevention of tuber- [illegible]

(2) they must avoid taking any course which might interfere with the action of the benevolent societies the object of which is to provide such dwellings. Baron von der Knesebeck, chamberlain to the Empress, said that the committee had done a great deal for male adults suffering from pulmonary tuberculosis but that it had not shown equal consideration for women and children. He had therefore been commanded to express Her Majesty's hope that additional sanatoriums for the reception of women and children would be provided. Professor Pannwitz then read the annual report on the sanatoriums, the Erholungsstätten,[1] the dispensaries, and other institutions with which the committee is connected. Professor von Leyden followed with a paper on the Efficacy of Sanatorium Treatment. After sketching the history of the movement for the prevention of tuberculosis in Germany he referred to the decrease in the mortality from that disease, a result which, he said, was in no small degree due to the sanatoriums. He was sorry to find that the sanatorium system had been unfavourably criticised by some medical men who seemed not sufficiently to have remembered that the lives of thousands of patients had been prolonged by means of the food, nursing, and medical care which they received in the sanatoriums and that the results would be still better if the patients could be permitted to make a longer stay in them. Sanatoriums, of course, were not a panacea, and their work required to be supplemented by other means such as the dispensaries, the Erholungsstätten, the asylums for incurable patients, and the seaside homes for children. In England and France pulmonary tuberculosis had also been successfully opposed by means of general hygienic measures, but the sanatorium system was not so well developed in these countries as in Germany where sanatoriums were established in connexion with the workmen's insurance clubs and were partly supported out of the funds of these institutions. In conclusion, Professor von Leyden advocated the compulsory notification of tuberculosis. Herr Gäbel, president of the Imperial Insurance Office, read a paper compiled from the enormous statistical material at his disposal showing that among 1000 men at various age periods who received sick pay under the workmen's insurance laws the proportion of those suffering from tuberculosis was 549 per 1000 from 20 to 24 years, 509 per 1000 from 25 to 29 years, and 429 per 1000 from 30 to 35 years; for the female sex the corresponding proportions were 425, 343, and 258 per 1000. There was a predominance of factory workers as compared with country labourers. The workmen's insurance institutions (Landes-Versicherungs-Anstalten) had provided for 16,489 patients
[illegible] m tuberculosis at an average cost per head of
[illegible] 17 15*s.*). Herr Pütter, town councillor of Halle,
[illegible] work of the anti-tuberculosis association there.
[illegible] the medical officer examined patients sent to
[illegible] resident of the association. Thermometers were given to them and they were shown how to take their temperatures, those who could not do this properly being visited at their homes by nurses and deaconesses connected with the association. The sputa were examined at the municipal laboratory free of charge. The patients also received printed instructions on the subject of hygiene and in certain cases money to be spent on food; they were also supplied with various articles of table service so that they need not have recourse to those which were used by the other members of the family. In the case of unmarried persons living alone the association took lodgings for them and disinfected the rooms with formalin from time to time. The whole town was divided into 28 districts in each of which a nurse or a lady visitor was appointed to look after the patients of the association. The association worked in harmony with the university clinics and other hospitals and also with the medical men who were quite willing to hand over the care of their poorer patients to the association. Dr.
[illegible] Berlin gave an account of what was being
[illegible] with especial reference to the voluntary
[illegible] berculosis and the proceedings terminated with a visit to the sanatoriums of the Berlin insurance institution (Landes-Versicherungs-Anstalt).

Medical Men in Parliament.

The number of medical men in the German Parliament has hitherto been smaller than in France and some other countries and the medical members of the Reichstag practise their profession only to a very limited extent. As medical interests have therefore but seldom received in Parliament an amount of consideration commensurate with the importance of the profession, it is a favourable sign that the number of medical men who have offered themselves as candidates at the forthcoming elections is greater than on former occasions. According to the medical journals the following members of the profession have been nominated in the places mentioned: Dr. Rügenberg in Bonn, Dr. Höffel in Zabern (Alsace), Dr. Krzyminski in Inowrazlaw, Dr. Bernstein in Torgau, Dr. Hollstein in Zittau, Dr. Mugdan in Görlitz, Dr. Leonhardt in Kiel, and Dr. Weyl in West Priegnitz. The candidature of Dr. Mugdan will be regarded with particular interest by medical men, as he is one of the founders of the "free-choice society" and holds a prominent position in the profession.

---

[1] Erholungsstätten are places where tuberculous patients spend the day in the open air, returning to their homes at night. There are several in the vicinity of Berlin.

May 25th.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE seventy-sixth session of the General Council of Medical Education and Registration was opened on May 21st at the office of the Council, Sir William Turner, K.C.B., the President, being in the chair.

The regular date for the summer meeting of the Council is on the fourth Tuesday in May, but this year, owing to Whit-Monday falling on June 1st, it was felt by the Executive Committee that if the Council met on the regular day the business probably could not be finished before Whitsuntide, hence the alteration of the date of the meeting.

The *personnel* of the Council has undergone some changes since the last meeting in November. Sir William T. Gairdner, owing to failing health, found it necessary to resign the representation of the University of Glasgow and the University appointed as his successor Dr. T. McCall Anderson, the professor of medicine. The period of office of Sir Hector C. Cameron, the representative of the Faculty of Physicians and Surgeons of Glasgow, has also expired since November last. Sir Hector Cameron having intimated that he did not intend to seek re-election Dr. John Lindsay Steven was appointed in his place.

Sir William Turner in his Presidential Address, of which we give an abstract elsewhere, after referring to the resignations which we have just mentioned, spoke as to the inspections which had been held of the examinations of the various licensing bodies. Other points to which he referred in his speech were the financial condition of the Council, the Medical Act of 1902 under which the Medical Council of Canada had been constituted, and the Bill which had been introduced and read the first time in the House of Commons for amending the penal and disciplinary powers of the Council and of the licensing bodies.

On Saturday, May 23rd, a discussion arose concerning the Pharmacy Bill promoted by Mr. Lough, M.P., Sir Hugh Beevor asking the President whether his attention had been called to the fact that the Bill contained no exemption of registered medical practitioners from its provisions and whether the Council should not take some steps with reference to this or any other Bill promoted on similar lines to see that the interests of medical practitioners are properly protected. We ourselves called attention in THE LANCET of April 4th, p. 982, to the fact that the Bill was against the interests of practitioners and finally the Council, on the motion of Dr. MacAlister, decided that the President should lay the matter before the Lord President of the Privy Council and should state that in the opinion of the General Medical Council the encroachment upon the rights of the medical profession ought not to obtain the sanction of Parliament. The interesting point about the discussion was the opinion of Sir Hugh Beevor and of Sir Victor Horsley that the matter was a proper one to be brought before the General Medical Council, but as we have previously pointed out the General Medical Council does not seem to have any legal status whatever as being a body for protecting the interests of the profession except in so far that it can purge the profession of offending members. Hence we are glad to see that the matter will be laid before the Lord President of the Privy Council, because of the weight of the opinion of this body with the Government.

The Council at the sitting on Monday, May 25th, took into consideration two penal cases, that of Dr. James Kirkland of 7, Ladbroke-square, W., and that of Mr. Edward John Smith. Both these gentlemen appeared in person, the case of the latter gentleman being an adjourned one. Dr. Kirkland undertook that he would not again repeat his conduct and it having been proved that Mr. Smith had given no grounds for complaint since his last appearance and that he had also undertaken to discontinue the practice complained of both gentlemen were informed that the Council would not proceed further against them. Other penal cases of a comparatively unimportant nature were proceeded with on Tuesday, May 26th.

THURSDAY, MAY 21ST.

The seventy-sixth session of the General Council of Medical Education and Registration was opened to-day in the premises at 299, Oxford-street, London, W. Sir WILLIAM TURNER, the President, was in the chair and there was a full attendance.

New Members.

The following official notifications were read by the Registrar (Mr. H. E. ALLEN):—

Glasgow, April 6th, 1903.

We, the Faculty of Physicians and Surgeons of Glasgow, in pursuance of the power given to us by the Medical Act (1886) do hereby appoint Dr. John Lindsay Steven to be a member of the General Council of Medical Education and Registration of the United Kingdom for the term of three years from the 6th day of April, 1903.

ALEXANDER DUNCAN, Secretary.

91, West Regent-street, Glasgow.

DEAR SIR,—I have to inform you that Sir William T. Gairdner, K.C.B., M.D., has intimated to the Court his resignation as representative of the University of Glasgow on the General Medical Council, and at a meeting held yesterday the University Court appointed Professor Thomas McCall Anderson, M.D., the University, Glasgow, in Sir William Gairdner's place for a period of five years from 14th May, 1903.

Yours faithfully,
ALAN E. CLAPPERTON,
Secretary, Glasgow University Court.

The Registrar, General Medical Council.

Dr. STEVEN was introduced to the Council by Dr. P. HERON WATSON and Professor MCCALL ANDERSON by Dr. D. W. FINLAY.

The President's Address.

In his address at the opening of the seventy-sixth session of the General Medical Council, the PRESIDENT commenced by referring to the reasons which had made it necessary that the Council should meet on a Thursday instead of the fourth Tuesday in May. He then mentioned with regret the resignation of Sir William Gairdner, who, he said, had that morning sent him a letter, the conclusion of which was as follows:—

> It only remains to me to ask you, as President, to be the means of conveying to my colleagues the deep sense of the kindness and consideration with which I have always been treated as the representative of the University of Glasgow, and my deep regret at the sudden termination of our always pleasant intercourse at the Council Board.

The President, continuing, offered the welcome of the Council to Sir William Gairdner's successor, Professor McCall Anderson, and went on to express the value which the Council attached to the services of Sir Hector Cameron, who had also resigned. To Dr. Lindsay Steven, his successor, the Council looked for a continuance of his predecessor's good work. The reports of the visitor and inspectors of the final examinations of all the licensing authorities with the exception of the Scottish universities had for the most part been received. The Scottish universities were to have been inspected during the summer but owing to the regrettable illness of Sir George Duffey, the Council's inspector, it remained for the Council to decide whether it would appoint a new inspector or hold the inspection over until next year in the hope that Sir George Duffey would then be able to undertake the task. This latter course, said the President, was the one which appealed to himself. The President continued:—With regard to finance, the Council will recollect that at the last meeting a report was presented by the Financial Relations Committee accompanied by a draft Bill to amend the Medical Acts, one of the objects of which was, by raising the fee payable on registration to a sum not exceeding £10, to augment the income of the Council so as to make it sufficient to meet the increase in its expenditure. On Dec. 2nd the Council resolved to refer the report and draft Bill back to the committee for further consideration and members of the Council were invited to make suggestions in regard to "economies in expenditure." Many suggestions have been received which have been grouped and summarised by our Registrar and circulated amongst the members of the Council. These will have to be considered by the Financial Relations Committee and reported on to the Council. I may recall to the Council that in a paragraph in the report of the Financial Relations Committee (Minutes, Nov. 29th, 1902, p. 137) it was stated that I had suggested that a memorial should be framed for presentation to the Privy Council in explanation of the condition of our finances. A memorandum on this subject which may serve as the basis of a memorial has been prepared and circulated amongst the members of the Council and I propose to ask you to consider it before the close of the meeting. In my address at the commencement of last session I called attention to the Medical Act, 1902, passed by the Canadian legislature, and approved by the King, under which a Medical Council of Canada was constituted. Power was given to establish a register of medical practitioners in Canada and to provide them with the status required for the establishment of reciprocal relations between the Dominion of Canada and the United Kingdom, such as on the one hand would enable practitioners with recognised Canadian diplomas to acquire the right of registration under our home Medical Acts and on the other would enable practitioners registered under these Acts to be admitted to the Canadian Register. In order to bring the Canada Medical Act into operation and to enable the Canadian practitioners to obtain the benefit of Part II. of the Medical Act, 1886, it is necessary *inter alia* that the provincial legislatures in Canada should renounce their present right of independent registration and consent to the formation of a register for the whole Dominion. From information which I have received it seems that at least one of the provinces is not prepared to adopt this course and so long as this attitude is maintained the whole Dominion of Canada will, under the present law, be excluded from the provisions of Part II. of the Act of 1886. It is much to be regretted that local influences should have interfered with the adoption of the Act throughout the Dominion, for as by Section 36 of the Medical Act, 1858, no person can hold any appointment as a physician, surgeon, or other medical officer in the military or naval service of the Crown, or fill certain civil appointments, unless he is on the Register of the United Kingdom, Canadian practitioners will therefore continue to labour under their present disability. Seeing that practitioners who possess diplomas granted in New Zealand and in three of the States of Australia, the universities in which confer medical degrees, are admitted to the Medical Register of the United Kingdom, and are thereby qualified to hold office in the public service, it is a matter for consideration whether something should not be done to put our Canadian brethren on an equal footing. Legislation to accomplish this purpose would not be complicated in its character. The 17th and 27th Sections of the Medical Act, 1886, Part II., might be so modified as to enable His Majesty by order in Council to declare that when a British possession is under both a central and a provincial or local legislature this part of the Act might apply to any province which, in the opinion of His Majesty, affords to the [illegible] ers of the United Kingdom such [illegible] His Majesty may seem just. A [illegible] Act in this direction is to be preferred to the proposal originally made by General Laurie in a Bill of last year again before Parliament, by which colonial practitioners would be admitted to our home Register without a corresponding equivalent being granted in the colony. But a second Bill, also introduced by General Laurie, provides the necessary modification should the Canadian Medical Act, 1902, not become operative. It would also in course of time bring all the provinces in a British possession into line, as any province which might at first be disinclined to concur would before long find that the medical practitioners within its area were placed at a disadvantage compared with those practising in adjoining provinces. The Bill prepared a few years ago at the request of the Council for amending the penal and disciplinary powers of the Council and the licensing bodies has been introduced into the House of Commons by our colleague Sir John Batty Tuke and read a first time. Its place as determined by the ballot is low down on the list and unless something unexpected arises to improve its position and to remove an opposition threatened by some Members of the House of Commons it is doubtful if it can make further progress during the present session. Mr. Norman King, one of the clerks in the office, has very usefully occupied his leisure by compiling on his own initiative an analytical index of the contents of our minutes from the year 1886 to 1902. Along with the index volume published in 1888 the Council will now have the means of referring to the subjects which have been under its consideration from its foundation in 1858 without the loss of time entailed in consulting the indices in the separate volumes. The Executive Committee has framed a motion on the matter which will be submitted to the Council by the chairman of business. The disciplinary cases to be brought before you during the session are unusually numerous and some of the offences alleged to have been committed are of a nature which seriously affect the character of the accused practitioners.

It was moved by Dr. MACALISTER, seconded by Mr. BRYANT, and carried by acclamation:—

> That the President be thanked for his address and requested to let it be printed in the minutes.

Business Committee.

On the motion of Dr. MCVAIL, seconded by Mr. BROWN, it was agreed that the following should constitute the Business Committee: Dr. MacAlister (chairman), Mr. Bryant, Dr. Bruce, and Sir Christopher Nixon.

A Question of Procedure.

Sir VICTOR HORSLEY at this stage of the business put a question with respect to the following notice of motion he had placed on the paper:—

> [illegible] of the examination in [illegible] t Examining Board in [illegible] London, and the Royal [illegible] h the remarks by the [illegible]

He wished to put the question to the Examination Committee. He understood that the customary procedure, which was that the chairman of the committee should draw up a draft report and send it round for consideration, had in this instance not been followed and he wanted to know why that procedure had not been followed.

The PRESIDENT: I think the Examination Committee will have a report.

Sir VICTOR HORSLEY: This session?

The PRESIDENT: I hope so; so far as the bodies have been inspected and so far as the Council has received their comments.

Sir VICTOR HORSLEY: We ought to have all these reports before us. The chairman of the Examination Committee ought to tell us why these were not circulated.

Mr. BRYANT, as chairman of the Examination Committee: The Examination Committee has not met to consider a report. It was understood that there would be no such report until all the papers, all the reports on primary education, could be obtained and considered together, so that the results could be compared.

Sir VICTOR HORSLEY declined to admit any understanding of the kind suggested. In the ordinary course the reports must be circulated and Mr. Bryant's explanation was not at all satisfactory.

The PRESIDENT: Well, go on with the next business.

Professional Medical Examinations.

The REGISTRAR presented annual tabulated statements for the year 1902 as follows:—

(*a*) Table showing results of professional medical examinations during 1902.

(*b*) Table showing results of professional examinations for qualifications in sanitary science, public health, or state medicine during 1902.

(*c*) Table showing results of professional dental examinations during 1902.

session of two days, costing [illegible]
of the Midwives Registration [illegible]

[illegible] o members has been sufficiently
[illegible] mber of members and not any
[illegible] Act of 1858 to be paid with the
[illegible] members The increase in the
[illegible] inevitably from the extended
[illegible] part also from the constantly
increasing size of the registers that are to be maintained and [illegible]

[illegible] connexion with questions of education and registration.

The widespread evils to the public resulting from unqualified practice—evils encouraged largely by the, at that time prevalent, employment by registered medical practitioners of unqualified assistants—then demanded attention and large sums have since that date been paid in legal expenses for the public benefit in successfully lessening such of those dangers as arose from the wrong conduct of members of the profession. Although the improper practice of employing unqualified assistants has been largely put a stop to, other forms of professional misconduct have arisen which have called for the attention of the Council [illegible]

[illegible] worse by the fact that its income is not growing. Practically the income of the Council and its branches is derived from registration fees. Owing to the efforts that the Council has made during recent years to benefit the public by improving medical education and by materially raising the standard of examination both in general and professional subjects the number of persons entering the profession and the fees for registration paid by t[illegible] If we
take the last two periods of ten years—
1893 to 1902—while 13,644 practitione[illegible]
period only 13,665 were registered in t[illegible]
79 The income, therefore, from fees [illegible]
what diminished and is not likely to [illegible]
that there has been a fall annually in the number of medical students for some years past. The average number of students entering during the period from 1879 to 1893 was 1708, but owing to the higher standard demanded and the increased length of a medical course the [illegible]

few exceptions, sufficient. since that year a regular deficiency has been annually disclosed as follows:—

	£ s. d.
1896	633 4 9
1897	1,538 9 8
1898	2,353 11 11
1899	1,573 14 6
1900	1,037 11 1
1901	1,608 12 0
1902	1,332 18 1
	10,033 1 11

Annual average deficit = £1433 5s. 11*d*.

[illegible] revenue.

It would not be for the welfare of the community that the long exerted efforts of the Council to promote the efficiency of the profession should be relaxed, nor would it be desirable that its vigilance should be less exercised in the discipline of the profession, however [illegible] other functions could be defrayed out of its present income mainly derived from registration fees. WM. TURNER, President.

May 1st, 1903.

In Camerâ.

The next items of business on the day's programme were: (1) To receive *in camerâ* a recommendation by the Penal [illegible] to a letter from Sir John Tuke on a penal case. The public accordingly were asked to withdraw and were not admitted to the council chamber during the rest of the sitting, which, in accordance with a resolution passed at an earlier stage of the proceedings, was not prolonged many minutes after four o'clock in the afternoon.

FRIDAY, MAY 22ND.

The Council resumed to-day, Sir WILLIAM TURNER, the President, being in the chair.

Proceedings *in camerâ*, which the President explained had not been concluded on the previous day, were continued.

The Dentists Register.

Mr. TOMES, on the admission of the public to the chamber, called attention to the inaccuracy of the Dentists Register by reason of its (1) not including all registrations; (2) in respect that a number of names had gone off it, though the persons bearing them were still living and practising at the same address; and (3) that a considerable number of names of persons who were dead still remained on the Register. He thought communication with the Pharmaceutical Society and other bodies might help to get the required accuracy.

The REGISTRAR explained the steps that were taken by him to secure accuracy and assured the Council that all voluntary help which they could obtain was availed of. He certainly should be glad to give attention to anything brought to his notice.

Apothecaries' Society of London.

On the motion of Sir HUGH BEEVOR, seconded by Mr. BRYANT, it was agreed—

> That Mr. Peyton Todd Beale, F.R.C.S., be appointed an assistant examiner in surgery to the Apothecaries' Society of London for a period of four years, vice Mr. C. Stonham, F.R.C.S., who retires by rotation.

Sir George Duffey's Illness.

Dr. MACALISTER moved :—

> That in consequence of the illness of Sir George Duffey, the Council's inspector of final examinations, the inspection of the examinations of the Scottish universities be postponed till next year.

He thought it was advisable to pass such a motion, so that Sir George Duffey might have the opportunity to finish the cycle of inspection and let the Council have reports that would be conformable. There was no great hurry in regard to the Scottish universities which he considered could safely be trusted to go on without Sir George Duffey's visitation for another year.

The motion was seconded by Dr. NORMAN MOORE.

Sir CHARLES BALL remarked that if the Council passed such a motion it would very much gratify Sir George Duffey who felt deeply his present inability to complete the work which the Council had intrusted to him.

After some words of appreciation of Sir George Duffey's work and services from Dr. BRUCE

The motion was agreed to.

Dr. ATTHILL, on behalf of Sir George Duffey, thanked the Council for coming to such a resolution.

Restoration to Medical Register.

It was moved by Dr. MACALISTER, seconded by Mr. BRYANT, and agreed to :—

> That the following report from the Executive Committee in regard to a suggested change in the Standing Orders be received and entered in the minutes—
>
> The Executive Committee have considered the following motion which on Dec. 2nd, 1902, was referred to them by the General Council with a request that they should consult the legal advisers of the Council on the subject: "That in the Standing Orders for the restoration of a name to the Medical Register, Chap. XVII., Clause 2. Subclauses 3, 4, and 5, the words Penal Cases Committee be substituted for the words Executive Committee." The Executive Committee, having consulted Mr. Muir Mackenzie on the subject of the motion, are advised that having regard to the special function of the Penal Cases Committee as defined by Chapter IX., Section 5, of the Standing Orders and to the powers of the Executive Committee under the Medical Acts, applications for restoration after penal erasure are most appropriately dealt with by the latter committee. The Executive Committee are therefore not prepared to recommend that the proposed change should be made in the Standing Orders.

Dental Business.

The REGISTRAR read the following report from the Executive Committee on the dental business transacted by it since the previous session of the Council.

> 1. The prescribed conditions having been duly fulfilled in each case, the names of the under-mentioned persons have been restored to the Dentists Register, from which they had been erased in conformity with the provisions of Section 12 of the Dentists Act, 1878: Alfred G. Annette, Walter Bennett, William V. Corbet, Henry W. Edmondson, Charles H. Fentiman, Joseph Hanreck, Frederick J. Lea, William Morris, Matthew H. Nisbet, Lawrence Read, George W. Roberts, Thomas R. Smart, and Francis Watts.
> 2. A question was considered by the committee from a medical practitioner respecting the position of practitioners in regard to the administration of anæsthetics for registered dentists acting for dental companies and they answered the inquiry by stating that the only answer they could give was to call his attention to the resolution of the Council in regard to the administration of anæsthetics.
> 3. The committee received from the Colonial Office an Act relating to the practice of dentistry in South Australia and referred it to the Dental Education and Examination Committee for their information.
> 4. A communication was also received from the Colonial Office seeking information as to the position of British dentists in Germany and the committee replied that: "Inasmuch as under the Dentists Act no provision is made for the establishment of reciprocal relations with foreign countries the Council has had no occasion to inquire into the privileges (if any) accorded to British dentists in Germany. German dental qualifications are not recognised as conferring any rights in this country. The committee would be obliged to receive from the Colonial Office any information on the subject which may be obtained through the Foreign Office."
> 5. The committee further received from the Colonial Office an Act to provide for the registration of dentists to practise in Queensland and referred it to the Dental Education and Examination Committee for their information.
> 6. They considered a complaint from a medical practitioner in regard to continued dental advertising by a registered dental student.
> 7. They considered also an application made on behalf of a Canadian dentist for registration in the Dentists Register and referred the matter to the Dental Education and Examination Committee for consideration and report.
> 8. The committee have also had under their consideration an application for registration under Section 37 of the Dentists Act by a dentist who was a pupil at the time of the passing of the Act.

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, this report was received and entered on the minutes.

Examination in Chemistry, Physics, and Biology.

Sir VICTOR HORSLEY had the following notice on the paper :—

> To call attention to the report by the visitors of the examination in chemistry, physics, and biology of the Conjoint Examining Board in England, of the Royal College of Physicians of London, and the Royal College of Surgeons of England, together with the remarks by the bodies inspected, and to move a motion thereon.

He said that before going on with his motion he should like to ask Mr. Bryant whether he was or was not going to present a report from the Examination Committee.

The PRESIDENT: There has been laid on my table this morning a report by the inspector and visitor of the examination of the Apothecaries' Society. That is a complete report of that particular examination.

Mr. BRYANT said that the matter was considered by the Examination Committee yesterday afternoon and it did not come to any definite conclusion about it. It certainly had not prepared a report to the Council, but if the Council was really desirous that some report should be brought forward the committee would be willing to do so. As the spokesman of the Examination Committee he had been asked to put to the Council the question whether it did really wish a report to be presented at the present time. In thinking the matter over last night he felt that the committee was in difficulty. In the report that had been presented to the Council the inspectors said, "We have not been able to compare this examination with any others of its own class, so that we are contrasting it with an ideal standard existing in our own minds." The inspectors should have something by which to make a standard of comparison. He understood that a report had been presented with reference to the Apothecaries' Hall, Dublin; he also understood that the inspectors had reported on the Scottish examination, and it occurred to him that now that these gentlemen had more information it would be more satisfactory if they could kindly give the Council a report with regard to the other bodies which they had already visited. He would like to propose that as the Irish body should be examined in June the Council should ask the two inspectors and visitors to report to it on the four bodies which they would have inspected. Then the Examination Committee should have something good to report upon; and he should have no difficulty in presenting a report which he trusted would be acceptable to the Council. When this report was first presented to him as chairman of the Examination Committee he felt that as the representative of one of the Royal Colleges it would be very difficult, if not quite impossible, for him to give an honest report bearing upon it. In the answers——

The PRESIDENT: You had better not go into the merits of the case at present. I understand that you are now giving your reasons for delay.

Mr. BRYANT: Very well; I shall not do so. I will simply conclude by moving:

> That the report be referred back to the visitors for further consideration and report, in view of the fact that subsequent to the date of their report the visitors have had an opportunity of comparing this examination with others of its own class.

Sir VICTOR HORSLEY: That is not an answer to my question at all.

Sir W. THOMSON: This motion by Mr. Bryant is not a proper one. Sir Victor Horsley has asked a definite question with reference to a specific performance by the Examination Committee. We have not got an answer, but instead of it Mr. Bryant has submitted a motion which is an entirely different thing.

Mr. BRYANT: I did answer the question of Sir Victor Horsley, though, perhaps, not directly. I said that the committee had not prepared a report upon this matter, but that it was willing to give a report if it was the express wish of the Council. I spoke as chairman of the Examination Committee and in that capacity proposed this motion.

Sir VICTOR HORSLEY: Really that is not an answer to my question! The standing orders provide that these reports shall go to the Examination Committee and that the Examination Committee shall report to this Council. That is the procedure. Mr. Bryant, instead of carrying out the usual procedure, took upon himself not to prepare a report on behalf of the Examination Committee for presentation to the Council to-day. Having done so he has put the Council in an entirely false position. Now I have asked for a direct answer to a direct question. I wish to know finally whether a report is going to be presented or not to this Council in the ordinary way during the present session?

Mr **BRYANT**: I have no report to present from the Examination Committee. But I have already said that it is willing to give a report if the Council specially ask for it

Sir **VICTOR HORSLEY**: It is not a question of willingness It is your duty. I want to know whether you are going to do your duty this session or not

Sir **JOHN TUKE**. May I ask how long this report has been in the hands of the committee?

Mr **BRYANT**. I can hardly say It has been in the hands of the Council for some months, but it has not been in the hands of the committee for so long The committee did not fully recognise that it would have to report upon it When the resolution was passed last session it was fairly understood that this report would not be considered until the other reports were before the committee.

Sir **VICTOR HORSLEY**. No, no I submit that six months is ample time for the chairman of the Examination Committee to have prepared a draft report which it was his duty to present to the members of the committee yesterday

Dr **FINLAY** said the point was whether the Council should wait until all the reports were complete and consider them together

Dr. **YOUNG** formally seconded Mr. Bryant's motion

Dr **WINDLE** said that he, as one of the inspectors, should absolutely refuse to take back the report If the motion was agreed to he should return the report identically in the same words, letter for letter If it was modified in any way it might be modified in a way which perhaps Mr Bryant did not desire But he absolutely refused to take it back

Mr **BRYANT** asked leave to withdraw his motion

Sir **VICTOR HORSLEY** objected to the motion being withdrawn until he had received an answer to his question

Dr **NORMAN MOORE** said that he could not vote for the motion The question before the Council was entirely one of business and expediency. Could time be saved by discussing [illegible] or should they arrive [illegible] the procedure sug[illegible]s a great deal to be [illegible] No self-respecting inspectors could take back their report with the view of modifying their statements It was not the function of the inspectors to correlate reports That was the duty of the Examination Committee He thought that the Council would save time if it were to discuss all these reports together and therefore he was opposed to Sir Victor Horsley's proposal

Sir **VICTOR HORSLEY**. I have made no proposal whatever.

Dr. **NORMAN MOORE** Well, I ought to have said notice of motion I think it would be a wrong course to send this matter back to the inspectors

Sir C **NIXON** urged on the Council to allow the motion to be withdrawn

On a division leave to withdraw was granted by 18 votes to 7

The **PRESIDENT** Well, we have come back to the point at which we started; do you propose anything, Sir Victor?

Sir **VICTOR HORSLEY** Certainly I move—

> [illegible] report during the [illegible] examination in [illegible]amining Board in [illegible]

This proposal was seconded by Dr **HERON WATSON** and was carried, 20 members out of 31 voting for it

Apothecaries' Hall, Dublin

Three reports on the final examinations of the Apothecaries' Hall, Dublin, were read by Mr **BRYANT** who presented them as chairman of the Examination Committee The first was in respect to an examination in July, 1902 (the inspector of which was Dr W. P. Herringham), and was as follows —

> Four candidates presented themselves for this examination One had been registered as a medical student in 1884 and had passed at the [illegible] authorities must conduct the whole examination of the candidate—that is, that he must be examined in all three subjects by one medical authority or combination of authorities" A second candidate having passed in medicine at the Hall received his Licence after passing in surgery and midwifery The third candidate presented himself in [illegible] He passed in medicine and [illegible]didate who presented [illegible] failed to pass in any [illegible] satisfacto[illegible] with the [illegible] standard [illegible] secretary [illegible] conductin[illegible] made wer[illegible] the inspector and examiners

Dr **MACALISTER** *reverted to the case of very exceptional* treatment of one of the candidates referred to in the foregoing, which he had called attention to on the previous day, and moved—

> That the President be requested to call the attention of the authorities of the Apothecaries' [illegible] the Examination Committee's re[illegible] and to state that in view of t[illegible] Council's advisers on the terms [illegible] regards the course taken by the [illegible]

Mr **BRYANT** seconded this motion

Mr **BROWN** pointed out that the case in question was a very unusual one He thought that another such was not likely to arise, the candidate had passed his examination in surgery before the passing of the Act of 1886 and he (Mr Brown) had yet to learn that that Act was retrospective

Dr **MCVAIL** asked Mr. Bryant if the Royal College of Surgeons of England gave a certificate for the "final" if a candidate passed in surgery at their examination

Mr **BRYANT**. I do not think so

Dr **MCVAIL**. Then how did this man get one?

M[illegible] at the document produced by [illegible]

[illegible] that case consideration of Dr MacAlister's motion should be postponed for the production by Mr Tichborne of the documents relating to the case He moved accordingly

Mr. **JACKSON** seconded the proposal which was agreed to

The second report read by Mr **BRYANT** *related to an* examination in October last It was.—

> There was but one candidate for the third examination, who had [illegible] In this examination he passed [illegible] agrees

The third report of the series was connected with examinations in January last which were conducted by the inspector, Dr W P Herringham, and the assistant examiners in surgery, Mr Alexis Thomson and Sir Henry Howse This report stated.—

> In the first examination there were two candidates One passed, the other was rejected in chemistry In the second examination there [illegible] passed In the third examination there was [illegible] standard of knowledge requir[illegible] is satisfied

All three reports were ordered to be entered on the minutes.

The University of Dublin

MR. **BRYANT** next read reports on the final examinations in the University of Dublin in May and June 1901, and November, 1902 the Council's visitor being Mr. Bryant and its inspector Sir George Duffey, M D.

The main report—that on May and June examinations—stated —

> The visitor and inspector report that the final or degree examinations of the University of Dublin are "sufficient" They draw attention to the fact that since the last visitation material changes [illegible]

> operative surgery assistance could be given by a past candidate to a [illegible] ring the presence of all [illegible] practice that seems to [illegible] in surgery both the visitor and inspector would have liked to see several doubtful candidates, who had shown weakness in the two cases allotted to them, further tested with a third or fourth case. In the examination in clinical medicine this method was freely used and with marked success.
>
> It is satisfactory to note that the time formerly allowed for answering the written questions and objected to at the former visitation as being too short has for some subjects been extended. But in other subjects—viz., surgery at the B.Ch. examination and in materia medica and therapeutics and in forensic medicine and hygiene—the limit is still much under the average time (half an hour for each question) recommended by this Council.

In respect to the November examinations the Examination Committee reported :—

> Section B of the first part of the final examinations of the University of Dublin was visited and inspected in November, 1902, at the express wish of the Council. The examination lasted four days; there were 21 candidates, one of whom retired after presenting himself at the oral examination in surgery. Every candidate is now orally examined in the presence of two examiners. The professors agree with the expressed opinion of the visitor and inspector that the supervision of the *vivâ voce* examinations is inadequate and recommend the board to take steps to make it efficient. Every written paper contained four questions and two hours were allowed to answer each paper. The oral examinations generally occupied from 10 to 15 minutes for each candidate, but there was no fixed time. The oral examination in medicine was conducted by the external examiner in the presence of the assessor, who is one of the professors of medicine in the university. The answering generally was poor.
>
> The oral examination in surgery was sound and practical. Both examiners examined each candidate and there were many museum specimens for use. The examinations in pathology and medical jurisprudence were altogether good. Of the 20 candidates who completed the examination 13, or 65 per cent., passed, and seven, or 35 per cent., were rejected. As a final conclusion, this supplemental visitation and inspection of November confirms the general opinion expressed in the report of May and June last, when the second part of the final examinations was visited and inspected: That the final examinations of the University of Dublin are sufficient.

These reports were received and entered on the minutes. An explanation in regard to faulty examination of one of the candidates was made by Dr. LITTLE and some discussion arose on a question which evolved as to the desirability of examining candidates rejected on a first examination who came forward on a second occasion without having in the interval taken the opportunity to study further. This matter was focussed by Mr. BROWN who, seconded by Sir VICTOR HORSLEY, moved :—

> That in the opinion of this Council it is undesirable that candidates who may have failed to obtain the minimum number of marks qualifying for a pass should be re-examined without bringing evidence of further study.

But discussion showed that it would be undesirable to press such a proposition and Mr. Brown withdrew his motion.

Election of Committees.

After agreeing to curtail the Saturday sitting by an hour so as to let committees have more time to prepare their reports the Council proceeded to ballot for the membership of the Executive Committee and the Penal Cases Committee. At the request of the PRESIDENT, Mr. Tomes and Dr. Lindsay Steven acted as scrutineers for ascertaining the result of the voting for the election of the Executive Committee and Dr. Atthill and Professor McCall Anderson as scrutineers for ascertaining the result in the election of the Penal Cases Committee. The President announced that the Executive Committee had been found to be constituted as follows: The President (*ex-officio*), Mr. Bryant, Dr. Payne, Dr. MacAlister, Dr. Pye-Smith, Dr. Heron Watson, Sir Charles Ball, and Sir Christopher Nixon, but that Sir John Batty Tuke and Dr. McVail had obtained the same number of votes for the second seat to be filled by a member belonging to the Branch Council for Scotland. The President next announced that the Penal Cases Committee had been found to be constituted as follows: The President (*ex-officio*), Mr. Bryant, Dr. Windle, Mr. Tomes, Sir Victor Horsley, Dr. Heron Watson, Sir C. Nixon, and Sir W. Thomson, but that Sir John Batty Tuke and Dr. Finlay had obtained the same number of votes for the second seat to be filled by a member of the Branch Council for Scotland.

Sir JOHN TUKE having asked that his name might be withdrawn in favour of Dr. Finlay, the PRESIDENT declared Dr. Finlay elected.

Six o'clock having arrived the election of a second representative for Scotland on the Executive Committee was postponed till Saturday.

The Council adjourned.

SATURDAY, MAY 23RD.

The Council resumed at two o'clock this afternoon, Sir WILLIAM TURNER, the President, being in the chair.

The Executive Committee.

The PRESIDENT called attention to the tie in the voting for a representative of the Scottish Branch on the Executive Committee. At the conclusion of yesterday's business, he said, and when a considerable number of members of the Council were not in the room, it was his duty to state that there had been a tie between Sir John Tuke and Dr. McVail. Dr. McVail was not in the room when he made that statement

Dr. MCVAIL said that he would have great pleasure in giving way to Sir John Tuke, the chairman of the Education Committee, who had rendered great services to the Council in the House of Commons. He considered it an honour to receive an equal number of votes with Sir John Tuke.

The PRESIDENT then declared that Sir John Tuke had been elected the second member of the Scottish Branch on the Executive Committee.

Sir JOHN TUKE thanked his old friend, Dr. McVail, for his great generosity in retiring in his favour.

The Pharmacy Bill.

Sir HUGH BEEVOR asked the President whether his attention had been called to the provisions of the Pharmacy Bill being promoted in the present session by Mr. Lough, M.P., and to the fact that the provisions of the Bill (*inter alia*) penalised any person other than a pharmaceutical chemist from dispensing medical prescriptions in a shop, the Bill containing no definition of the word "shop" and no exemption of registered medical practitioners from its provisions; and, further, whether in view of this, the Council should not take some steps in reference to this or any other Bill promoted on similar lines, to see that the interests of medical practitioners were properly protected.

The PRESIDENT said that he was indebted to Sir Hugh Beevor for sending him a copy of the Bill. He had gone through the Bill and he thought that before he could attempt to give anything like an answer to the question now submitted to him it was necessary that he should look into the Pharmacy Acts which the Bill proposed to amend so that he might see what the differences were between the Bill and those Acts. There were two Acts of Parliament bearing upon pharmaceutical chemists. One was the Act of 1852 which regulated the qualification of pharmaceutical chemists. That Act had only to do with pharmaceutical chemists and medical practitioners were expressly excluded from it. Then there was the Act of 1868 which was an Act to regulate the sale of poisons. The principal enacting clause in that Act was as follows: "It shall be unlawful for any person to sell, or keep open shop for retailing, dispensing, or compounding, poisons, or to assume or use the title chemists or druggists." But subsequent sections of that Act reserved the rights of legally qualified apothecaries, Members of the Royal Colleges, and wholesale dealers in supplying poisons in the ordinary course of dealing. In Section 17 occurred this expression: "Nor shall any of the provisions of this section apply to any poisons supplied by a legally qualified medical practitioner to his patients." But there was a subsequent Act passed in 1869 which set forth that "nothing contained in the first 15 sections of the recited Act of 1868 shall affect any person who has been registered as a legally qualified medical practitioner before the passing of this Act and the said clauses shall not apply to any person who may hereafter be registered as a legally qualified medical practitioner." He thought he might say that these three Acts did guard the interests of the medical profession and the question naturally arose whether in the Bill now before Parliament the interests of the medical profession were still being preserved. He would point out that the Bill was a Bill to alter and to amend the Pharmacy Acts of 1852 and 1868 and the question arose—Would the sections of these Acts to which he had referred still be in active operation or be annulled by the passing of this Bill? That was a legal question and he did not profess to answer it. But there were one or two points in the Bill to which he might refer. The Bill applied to Great Britain—England, Scotland, and Wales—but Ireland was expressly excluded. The definition clause was important: "In this Act 'the Society' shall mean the Pharmaceutical Society of Great Britain; 'registered person' shall mean a pharmaceutical chemist or a chemist and druggist; 'poison' shall mean a poison within the meaning of the Pharmacy Act, 1868; '*registrar' shall mean the registrar of the Society.*" Section 2 of the Bill seemed to him to enlarge very materially the Pharmacy Acts in a very important direction:—"It shall be unlawful for any person or any company, firm, co-partnership, or body of persons, to keep any open shop or shops for the retailing, dispensing, or compounding of poisons or of medical prescriptions unless each shop shall be *bonâ fide* conducted by a registered person." That was a very important provision. The existing Act was for regulating the sale of poisons, but by this Bill not only was the sale of poisons to be regulated but the compounding of medical prescriptions also and the clause went on to say: "or to permit or suffer in such shop any poison to be retailed or any medical prescription to be retailed, dispensed, or compounded otherwise than by, or under the supervision of, a registered person." And a "registered person" was a person registered under this Act or under the Pharmacy Act—namely, a pharmaceutical chemist or a chemist and druggist, not a medical practitioner. That, he submitted, was a very serious inroad on the rights of the medical profession, and, so far as he could see, there was no provision in the Bill to safeguard medical practitioners. The question very materially affected the Society of Apothecaries and he should like to know whether that society was not prepared to get a legal opinion on the Bill. He did not know why the General Medical Council should go to the expense of obtaining a legal opinion in the first instance. He thought it was rather the Society of Apothecaries that should do so.

Sir HUGH BEEVOR said that he had brought the subject before the Council as a matter of public interest. He was not asked to bring it forward by the Apothecaries' Society but he considered that it ought to come before the Council in the interests of the profession.

The PRESIDENT said that there was one branch of the profession which was peculiarly affected—namely, the Society of Apothecaries—and he thought it might help the Council if the Society of Apothecaries were to get a legal opinion as to the exact signification of the Bill and how far the rights of medical practitioners were affected by it.

Sir VICTOR HORSLEY said that the Bill arose out of the report of a departmental committee. The British Medical [illegible] the Bill affected the whole [illegible] it was a very proper matter [illegible]

The PRESIDENT: I am not objecting to the raising of the question here, but I think a legal opinion should first be got by the Society of Apothecaries.

In answer to a question by Dr. HERON WATSON,

Sir JOHN BATTY TUKE said there was not the slightest chance of the Bill passing this session. It had not reached the second reading and if it ever did it could only do so if unopposed, and even if it were unopposed it would have to go to the Standing Committee on Law, which would be sufficiently occupied for the rest of the session with the Deceased Wife's Sister Bill.

Dr. MACALISTER moved:—

> That the President be requested to [illegible] the Lord President [illegible] Council this encroachment ought not to obtain the sanction of Parliament.

Sir HUGH BEEVOR seconded the motion.

[illegible] said that for many [illegible] London had been [illegible] its statutory duty to provide qualified dispensers for medical men, but this had not been done and it had allowed the Pharmaceutical Society to come in and to take its place.

Dr. MACALISTER'S motion was agreed to.

Results of Examinations.

Sir CHARLES BALL moved:—

> That the report of the Examination Committee upon the desirability of obtaining additional information from the various licensing bodies for use in the preparation of the annual table (a) showing results of professional examinations which was received by the Council and entered on the minutes and appears as Appendix XXII. of the volume [illegible] at [illegible] to [illegible]

He said that the annual table gave no information which they could rely on as to the passes and rejections for the simple reason that since 1864, when these returns were first directed to be made annually, the examinations had become so complicated and involved that it was impossible to present the information in a useful form in a table such as that now prepared.

Mr. BRYANT, in seconding the motion, said that the additional information asked for would be very valuable if they could obtain it from the licensing bodies.

The motion was agreed to.

University Representation on the Council.

Mr. JACKSON moved:—

> That the Council petition the Privy Council that, in the event of the Victoria University (Manchester) being divided into two or more separate universities, a single representative should represent the whole collectively.

He thought everyone would agree that the Council was sufficiently large to discharge the duties that were imposed upon it and there were various reasons why the membership should not be increased. Whenever any proposal was made for increasing the number of Direct Representatives it was always alleged as a reason against it that the Council was large enough already, that the accommodation was not sufficient, and that additional members would necessarily lead to increased expense, which was very undesirable in the present financial position of the Council. There was a proposal to divide the Victoria University into two or more separate universities and if that was done each of these bodies might desire to have a representative on the Council. There would be a new university for Liverpool and before very long there might be a fresh university for Yorkshire—in fact, universities seemed to be springing up almost like mushrooms and they might all claim to have a representative on the Council. It was not desirable, he submitted, that every new body which was created should necessarily have a member to itself on the Council. They must be content with a portion of a member; otherwise the members of the Council would be increased to undue proportions.

Mr. BROWN seconded the proposal, remarking that if the university representation was to go on increasing the Council would have to make application to the Government for a considerable increase in the number of Direct Representatives. He did not think the time had arrived when newly created universities should be accredited with a member each on the Council.

The PRESIDENT said there were two matters they had to consider in connexion with the foundation of a university and the granting to that university of representation on the General Medical Council. The charter founded the university, but the Privy Council, which granted the charter, had no power to give the university a representative on the General Medical Council. The General Medical Council was a Parliamentary body; it was constituted by Parliament and to introduce a new member on the Council meant a new Act of Parliament. The Privy Council could not do it; Parliament alone could do it. What was done in the case of the University of Birmingham was to apply to Parliament for an Act. The date of the charter was March 24th and the Act received the Royal assent on May 25th, practically two months subsequent to the charter having received the Royal assent. In discussing this question he wished it to be kept clearly before the minds of members that anything which was done in the way of giving an opinion as to a representative to be appointed under a change in the constitution of Victoria University was to be done through Parliament and not through the Privy Council.

Dr. WINDLE said that none of the new universities would be capable of giving a registrable qualification until they obtained a special Act of Parliament.

The PRESIDENT informed the Council that no Bill had yet been introduced. But if a Bill was introduced, to whom should they present a petition—to the Privy Council or to Parliament?

Dr. MCVAIL considered that the discussion of the matter at this moment was altogether out of order. The General Medical Council had simply to administer certain Acts of Parliament [illegible] Privy Council to the General Medical Council the latter would then be quite entitled to give an opinion, but he held that they had no right whatever to enter into consideration of possible Acts of Parliament.

Sir JOHN BATTY TUKE agreed that it was hardly in order to discuss a Bill that did not exist. Should one be introduced he should move in the House of Commons the rejection of the clause giving a separate representation if there was such a clause in it.

Dr. PYE-SMITH asked the President to rule whether the discussion was really out of order.

The PRESIDENT: This is a matter that affects the Council's constitution and I think we have a perfect right to express our opinion on it. If there was a Bill before Parliament we should have a right to petition about it. We believe that a Bill is ready but it cannot be presented until the charter is signed. The charter is not yet signed. Therefore, my ruling would be that we are right in discussing this matter.

Dr. PYE-SMITH said that in that case he was prepared to move an amendment because he thought the motion did not go far enough. He agreed that the number of members already was inconveniently large and it was a great evil to increase it by giving separate representations to any new universities that might arise, say, in Liverpool, Leeds, Bradford, and Bristol, all of which had been spoken of. He moved—

> That the President be requested on the first opportunity to urge upon the Government the importance of reducing the number of the members of this Council.

Dr. PAYNE seconded and Dr. MACALISTER supported the proposal.

Sir CHRISTOPHER NIXON said that if Dr. Pye-Smith's amendment meant that the number of members should be diminished by a system of grouping the universities so that one person might represent a group of two or three or four he certainly should oppose it because it was not to be expected that the two chief universities of Ireland would be satisfied with less representation on the Council than they had at present. At the same time he would not object to the adoption of a grouping system in respect to new universities.

Dr. WINDLE did not see any reason why at least the three Scotch bodies giving the same registrable qualification should not be grouped under a single representation. He, however, should oppose any plan to disfranchise any, and especially the younger, universities which had power to give a registrable qualification.

Dr. FINLAY intimated that he should vote against the amendment. With respect to grouping, if they combined the universities and licensing bodies of Scotland would they group together, say, the Universities of London and Oxford? Before the Council committed itself it should have before it some very definite scheme of representation.

Dr. NORMAN MOORE thought that if they had a definite scheme before them they could discuss its details, but merely to talk on the abstract question as to whether the Council should be diminished or increased seemed to him to be a waste of time. He did not regard with apprehension an increase of universities; any such increase was sure to do a lot of good to the country and in his view it would be objectionable to deprive new bodies of direct representation.

Sir VICTOR HORSLEY in supporting the amendment said that it crystallised the feeling that this Council was not a representative council at all, so far as the representation of the universities was concerned.

Mr. JACKSON was glad that he had brought forward this matter because it had elicited much of the opinion of the Council. He should be pleased if either the motion or the amendment were passed, but he did not propose to withdraw his proposal in favour of the amendment.

On a division the amendment was rejected by 16 votes to 9.

Dr. MCVAIL wished to move another amendment to the motion, but he objected to go on with it that day because even at the minute he was speaking the Council was sitting beyond the time allowed by the standing orders.

The Council adjourned till Monday.

MONDAY, MAY 25TH.

The Council resumed its sittings to-day, Sir WILLIAM TURNER being in the chair.

Instead of continuing the discussion on Mr. Jackson's motion which was before the Council at its rising on Saturday it was decided to proceed with the penal cases.

The Case of Dr. James Kirkland.

Consideration was first given to the case of James Kirkland of 7, Ladbroke-square, W., registered as M.B., Mast. Surg., 1895, Univ. Glasg., who had been summoned to appear before the Council to answer the following charge, as formulated by the Council's solicitor:—

> That being a registered medical practitioner you have been, and are, a party to the publication of advertisements circulated in pamphlets on social purity purporting to contain advice to young persons, informing the public that the authors of the pamphlets have secured the coöperation of a well-known physician who has for years made the nervous and physical conditions which evil habits bring about a special study and whose charge is moderate, and inviting the public to apply for your address, and to the issue to persons who answered the advertisement of lithographed forms, stating your name, address, and hours of consultation, and that you are the physician recommended in the pamphlets.

Dr. Kirkland appeared, accompanied by his counsel, Mr. William B. Campbell, instructed by Messrs. Edwin Smith and Ellis, solicitors, Bedford-row.

The complainants, the London and Counties Medical Protection Society, Limited, were represented by Dr. H. Woods, their general secretary.

Mr. WINTERBOTHAM, solicitor to the Council, read the charge.

Dr. WOODS, in opening the case, stated that the pamphlets referred to were cheap publications sold at various small shops and particularly at the late Mr. Kensit's place in Paternoster-row. They were unspeakably filthy and there could be no doubt that Dr. Kirkland was the physician referred to in them. The statutory declarations before the Council made it perfectly evident that Mr. Kensit represented that Dr. Kirkland was the person he wanted to recommend, and when patients went to Dr. Kirkland he charged a medical practitioner's fee. Whether authorised by Dr. Kirkland or not, he had been perfectly well aware of the publications; he had taken advantage of them by treating patients who had come to him through them and had made no effort whatever to stop them.

The statutory declarations in support of the charge were held as read.

Mr. CAMPBELL, in defence, said that the charge was that Dr. Kirkland had been guilty of self-advertisement. It came as a surprise to him that Dr. Woods added to the charge that the medium in which the advertisements appeared were objectionable as the pamphlets contained obscene passages. It would have been fairer if he had been previously told of this addition to the charge, but the answer was that Dr. Kirkland was not responsible for these pamphlets, that he never knew of their existence until the present charge was brought, and that he was not the physician referred to in them. Consequently he (Mr. Campbell) was not called upon to defend the Kensit pamphlets. With respect to a pamphlet published for Mr. Henry Varley, which contained an announcement similar to that objected to in the other publications, that publication was strictly proper and Dr. Kirkland would not in the slightest degree deny that he gave his name to Mr. Varley for certain limited purposes only, he being an old friend of Dr. Kirkland's wife. Mr. Varley's book had been published first in 1883—a time at which Dr. Kirkland had not commenced the study of medicine—and it contained the announcement objected to and so Dr. Kirkland could not be the physician referred to. If he was not the physician how was it possible for the three persons who had made statutory declarations to get his name and address? It came about in this way. Mr. Varley was frequently away from town. He asked Dr. Kirkland to let his publisher have his name and address in print and Dr. Kirkland supplied lithographed forms. But to treat that as wholesale self-advertisement would be really trifling with common sense. Dr. Kirkland had not had the slightest idea that these forms were to be used in connexion with any printed pamphlets. How came it that Mr. Kensit, as well as Mr. Varley, recommended Dr. Kirkland? Simply in this way, that when Mr. Kensit published one of the pamphlets which had been named by Dr. Woods he, without Dr. Kirkland's authority, imitated Mr. Varley. Dr. Kirkland had never been warned of what was going on, but so soon as complaint was made he gave not only verbal but written instructions to have all his lithographed forms destroyed. At this moment Dr. Kirkland was willing to give the most distinct undertaking that the thing should not happen again.

Statutory declarations in defence previously lodged with the Council were taken as read.

Dr. KIRKLAND then gave evidence in his own behalf. In answer to Mr. CAMPBELL he stated that he came to practise in London in 1899. He met Mr. Varley, whom he knew to be interested in social purity matters, in September of that year, having to attend him professionally, and it was then for the first time that Mr. Varley broached his wish to have witness as a physician he could recommend. At that time witness did not know anything of Mr. Varley's book and he never authorised Mr. Varley or his publisher to use an advertisement he might have the advantage of. As a matter of fact, when he knew of the book he did not know that the announcement in respect to a physician referred to himself. He had never seen the Kensit pamphlets until the letter of the registrar of the Council reached him and he did not know John Kensit. He had never been in communication with the social purity people in London, and if the announcement in the Kensit pamphlet actually referred to him he did not know it. He certainly knew of the Council's rule as to advertising. He had never advertised. He did not think that the giving of lithographed forms to save other people the trouble of writing his name and address was an infringement of the rule in question. He certainly never agreed that these forms should be given for Mr. Kensit's use. He had ordered the forms and he paid for them. If these forms were in circulation in February it was not to his knowledge, for he had ordered their destruction in October, he thought. He had had no patients through them since October, 1902.

Mr. CAMPBELL: You do sincerely regret that an offence has been committed and you intend not to repeat it?

WITNESS: Certainly.

Dr. MACALISTER: Did you make every effort to get these pamphlets suppressed?

WITNESS: No; I have nothing to do with them; I did not know of their existence until I heard from the Council.

In answer to Dr. MCVAIL, witness said that everything he had done in connexion with the lithographed forms had been done through Mr. Varley, to whom he gave them to circulate to whomsoever he liked. He had prescribed to country patients by letter without seeing them if he thought that it could safely be done.

Mr. ALFRED HOLNESS, publisher of Mr. Varley's book, was next examined. He testified that he got 200 or 300 of the forms in question. Mr. Kensit had come to him and said that he was dissatisfied with the physician he had been recommended, and he asked witness if he would have any objection to send the circular which he indicated that he knew had been prepared for Mr. Varley and witness had replied, "Certainly not." The reason he gave Mr. Kensit for saying so was this, that many of the letters received by him on Mr. Varley's behalf showed him that many young fellows were brought under the influence of quacks and he felt that if they could be brought into contact with a regular practitioner instead it would be advantageous. He had no authority to give away the circulars to Mr. Kensit or on behalf of that gentleman. At the time he complied with Mr. Kensit's request he did not realise the seriousness of the position in which he might be putting Dr. Kirkland in the way in which he had realised it to-day after hearing the evidence. He took all responsibility for the sending out of any of Dr. Kirkland's forms subsequently to October last. Ever since he had been acquainted with the matter—now 20 years or so—Mr. Varley's pamphlet had contained the information that there was a physician whose name and address could be got on application.

Mr. HENRY VARLEY was also called. He confirmed the statutory declaration which he had made and in cross-examination he declared that the paragraph in his book complained of had no distinct reference to Dr. Kirkland whose wife he had known since childhood. In 1902 he knew that Dr. Kirkland was being recommended to applicants who had read his book, but he never mentioned to him that his name was being so used.

The Council deliberated on the case *in camerâ*. On the readmission of the public,

The PRESIDENT, addressing Dr. Kirkland, said: The Council understands that counsel, acting on your behalf, has given the undertaking that you will come under the obligation to cease this conduct in connexion with the charge made against you. Will you state that that is so?

Dr. KIRKLAND: Yes, sir.

The PRESIDENT: Then I have to communicate to you the following resolution:—

> 1. The facts alleged against you in the notice of inquiry have been proved to the satisfaction of the Council. 2. Seeing, however, that you have expressed your regret that you have committed what the Council regards as a grave professional offence and that you have promised to abstain from any conduct affording similar ground of complaint for the future the Council has resolved not to proceed any further in reference to the facts proved against you.

The Case of Mr. Edward John Smith.

The Council proceeded to the consideration, adjourned from Nov. 26th, 1902, of the facts proved against Edward John Smith of 110, Balsall Heath-road, Birmingham, registered as Lic. Soc. Apoth. Lond., 1883, Mem. R. Coll. Surg. Eng., 1885, who had been summoned to appear before the Council to answer the following charge, as formulated by the Council's solicitor:—

> That you have been guilty of infamous conduct in a professional respect, the particulars of which are as follows: That you, being a registered medical practitioner, systematically seek to attract practice by a system of extensive public advertisements containing your name, address, and qualifications, and invitations to persons in need [illegible] advertisements so [illegible] of a character dis- [illegible]

[illegible] ncil on this case on [illegible] uncil addressed Mr. [illegible] very carefully on [illegible] t the facts alleged [illegible] en proved to the [illegible] u this decision the [illegible] a serious view of [illegible]

Mr. Smith attended in answer to the summons.

Dr. Bateman appeared on behalf of the Medical Defence Union, the complainants.

Mr. WINTERBOTHAM having read the notice to attend, Dr. BATEMAN stated that he had no further evidence to offer against Mr. Smith and that he was perfectly satisfied as to his conduct in the interval since last session.

Mr. SMITH, in answer to the PRESIDENT, stated that he had discontinued the practice complained of and he undertook not to repeat it in the future.

After a short deliberation in private,

The PRESIDENT, addressing Mr. Smith, said: Mr. Smith, the Council has deliberated on your case and relying on your statement and promise has resolved:—

> That the Council, having further considered the facts proved against you, does not judge you guilty of infamous conduct in a professional respect.

Mr. SMITH: I should like to address a few words to you.

The PRESIDENT: No, no. We cannot hear you; your case is closed.

Amendment of Medical Acts.

Mr. TOMES asked a question in regard to the terms of General Laurie's Bill to amend the Medical Acts, to which the President had alluded in his address.

The Registrar was directed to procure copies of the Bill for the information of the Council.

The English Conjoint Board's Examinations.

Sir VICTOR HORSLEY asked a question as to the progress made by the Examination Committee in the preparation of the report on the visitation and inspection of the primary examinations of the English Conjoint Board.

As Mr. Bryant was absent other members of the committee stated in reply that the chairman of the committee had promised to prepare a draft report for the consideration of the committee on Wednesday, May 27th.

The Council adjourned.

TUESDAY, MAY 26TH.

The Council continued its sittings to-day, Sir WILLIAM TURNER again presiding.

The Case of Dr. J. Dugald Maclean.

Consideration was given to the case of James Dogald Maclean, of 72, Summer-hill-road, Birmingham, registered with the triple qualification of Scotland, 1893, and M.B. Mast. Surg., 1893, Univ. Edin., who had been summoned to appear before the Council to answer the following charge, as formulated by the Council's solicitor:—

> [illegible]

Dr. MACLEAN appeared, being accompanied by Dr. WOODS, secretary of the London and Counties Medical Protection Society, Limited.

Mr. WINTERBOTHAM stated that the complaint had originated with a public board—the Birmingham School Board.

The PRESIDENT asked Dr. Maclean if he was represented.

Hospital, Dental Department; Theodore James Gayton Fielder, William Douglas Frew, Leonard Anderson Glaisby, Duncan Henry Grubb, Arthur John Haddock, and Samuel Hallam, Royal Dental Hospital, London; Arthur William Gant, Arthur Tidswell Hanson, and Sidney Harlock, Victoria Dental Hospital, Manchester; Arthur Hammond-Smith, William Alfred Helyar, and Percy Harold Hickman, and Frank Alfred Husbands, Guy's Hospital, Dental Department; Wilfrid Harvey, National Dental Hospital; John Garnet Hemsted, Frank William Herbert, Albert Oliver Macarius Heslop, and Herbert Henning James, Royal Dental Hospital, London; John Joseph Horton, and John Robertson Knott, Dental Hospital, Birmingham; Arthur George Lacey, Royal Dental Hospital, London; George Edward McMahon, Dental Hospital Liverpool; Philip Edwin Luce, James William Mawer, Norman McLeod Nibbs, Herbert Arnold Pallant, Henry Maurice Peacock, Henry Garfield Pearce, Edward Laurence Pilbeam, and Herbert Poyton, Guy's Hospital Dental Department; William Charles Augustus Ovey, Albert Pfeiffer, Charles Read, and George Theodore Robinson, Royal Dental Hospital, London; Harold Ridges Rowe, National Dental Hospital; Ronald Maclean Rowstron, Newcastle-on-Tyne Dental Department, Durham; Harold John Russell and John Francis Ryder, Guy's Hospital, Dental Department; Christopher John Storey, National Dental Hospital; Harold Foster Strickland, George Frederick Taylor, Frank Throp, William Collingwood Tuck, Royal Dental Hospital, London; Frederick Vosper, National Dental Hospital; James Herbert Williams and William John Wormald, Guy's Hospital, Dental Department; Francis Raymond Wilson, National Dental Hospital; and Aubrey Geer Wootton, Royal Dental Hospital, London.

I. Allaun, R. F. Hayes, T. J. Brooke-Kelly, and P. D. Sullivan.

TRINITY COLLEGE, DUBLIN.—At examinations held at Trinity term the following candidates were successful :—

Final Examination in Surgery.—William G. Harvey, William R. P. M'Neight, Robert J. Fleming, Reginald H. Lee, John M. Holmes, Henry O'H. May, Alexander L. Otway, John H. Askins, Douglas B. Thomson, David C. Pearson, Reginald W. T. Clampett, Alexander H. Marks, Samuel H. Vickery, Harry R. Nelson, Augustus B. Tighe, and Bertram L. Middleton.

FOREIGN UNIVERSITY INTELLIGENCE — *Gratz:* Dr. Lorenz of Vienna has been appointed to the chair of Clinical Medicine.—Dr. Knauer of Vienna has been offered the chair of Gynæcology in succession to Dr. Rosthorn who goes to Heidelberg.—*Iurieff (Dorpat):* Dr. Savelieff, Extraordinary Professor of Medicine, has been promoted to the full professorship.—*Jena:* Dr. Bernhard Krönig of Leipsic has been appointed to the chair of Midwifery and Gynæcology in succession to Dr. Schultze, resigned.—*St. Petersburg (Military Medico-Chirurgical Academy):* Dr. V. Orlovski has been recognised as *privat-docent* of Medicine and Dr. Hagen-Torn as *privat-docent* of Surgery.—*Vienna:* It is now announced that Professor Flügge has declined the offer of the chair of Hygiene.

ROYAL MEDICAL BENEVOLENT COLLEGE.—At the annual general meeting held on May 29th at the office of the College in Soho-square, London, W., the following candidates for pensionerships and foundation scholarships were declared to have been duly elected :—

To Pensionerships.—Frances Newsam (Pugh Pensioner), Elizabeth M. Smith, Harriett C. Addison, Margaret A. Mayhew, and Catherine A. Cringle.

To Foundation Scholarships.—Roy G. Shapley, Eric S. Monro, Edward Cooke, Arthur W. Barr, John A. Caw, James L. Taylor, Sydney D. Newton, and John A. R. Campbell.

UNIVERSITY OF LONDON: FACULTY OF MEDICINE.—A meeting of the Faculty of Medicine was held at the University on May 22nd. Mr. H. T. Butlin, the Dean of the Faculty, was in the chair and 40 members were present. The Faculty had under its consideration a proposal by the board of studies in dentistry to institute a special degree in that subject. Two schemes for a curriculum and examinations were submitted. The scheme recommended by the majority of the board required that all candidates for a dental degree should previously have obtained the degrees of M.B., B.S. of the University. The minority scheme required all candidates to have passed the intermediate (M.B.) examination of the University before submitting to the special examination. Full details of each scheme were circulated before the meeting, together with a copy of a petition from the Royal Dental Hospital and National Dental Hospital to the University of London Statutory Commissioners praying that a degree in dentistry should be established. It was moved by Mr. Badcock and seconded by Dr. Lauriston Shaw "That it is desirable that the University of London should institute a degree in dentistry." As an amendment it was moved by Mr. Morton A. Smale and seconded by Mr. W. A. Maggs, "That after consideration of the report of the board of studies in dentistry the Faculty of Medicine is of opinion that it is not desirable at present to establish special degrees in special departments of medicine and surgery." The amendment was carried by 16 votes to 13 and was subsequently adopted as a substantive motion.

THE LEAGUE OF MERCY.—On May 22nd the Prince and Princess of Wales entertained a number of presidents, vice-presidents, and members of the League of Mercy at Marlborough House, when an investiture of the order took place. According to the charter under which the League of Mercy was founded in 1899 its object is to further the interests and to promote the adequate maintenance of hospitals and other institutions for the relief of sickness and suffering, and this was to be done especially by encouraging personal service on the part of large numbers of persons. The League of Mercy has, in the four years during which it has been in operation, contributed £22,000 to King Edward's Hospital Fund, and this part of its work appears to be now established on a firm basis with progressively increasing results. Moreover, the additional £100,000 or £150,000 per annum which the King's Fund was initiated to secure for the hospitals seems to be within measurable distance of being attained. Suggestions have from time to time been made to the effect that it would be fully in accord with the objects and name of the League of Mercy if those who are willing and able to render personal aid to the inmates of hospitals and kindred institutions could be brought together and coördinated under its supervision. In other words it is proposed to establish a "Samaritan Wing" or department of the League of Mercy. The proposal, if found practicable, has the sanction of the Grand Presidents their Royal Highnesses the Prince and Princess of Wales and the approval of His Majesty the King. The work of the league is carried on by a network of branches spread over London and the home counties. Nearly every Parliamentary division within this area has its branch of the league, but even yet the organisation of its machinery is not completed. Nearly every one of the 100 districts into which London and the home counties have been divided now has its branch of the league at work Among those who were awarded the Order of the League were the following medical men Dr Clement Godson, Mr Norman Hay Forbes, Mr T F McDonnell, and Mr H Wright

EXMOUTH HOSPITAL —At a three days' bazaar which has just been held at Exmouth over £1000 were raised towards the building fund of the Exmouth Hospital

DONATIONS AND BEQUESTS —By the will of Mr William H Cope University College Hospital, London, will receive £100

MEDICAL MAGISTRATE —Dr Thomas Sheldon has been placed, on the nomination of the Lord Lieutenant, upon the commission of the peace for the county of London

REMUNERATION FOR EXTRA SERVICES —The Bristol board of guardians on May 22nd awarded 20 guineas to Mr R H Norgate, the resident medical officer of the Stapleton workhouse, in recognition of his services in attending patients at the Broom Hill Fever Hospital

LITERARY INTELLIGENCE — Messrs Baillière, Tindall, and Cox announce that they will this week issue a new volume in their University Series—viz, "A Manual of Medicine," by Professor T Kirkpatrick Monro In addition to the foregoing they announce a monograph on "The Imperfectly Descended Testis," by Mr W McAdam Eccles, and a new work by Mr J Jackson Clarke on "Protozoa and Disease"

OPENING OF KEW BRIDGE —Mr. Joseph Smith, M.R.C.S Eng, chairman of the Chiswick urban district council and late honorary surgeon of the Royal Surrey County Hospital, had the honour of being presented to their Majesties the King and the Queen on the occasion of the opening of Kew Bridge on May 20th Mr Smith at the same time presented to the King on behalf of the inhabitants of Brentford and Chiswick a silver tankard, a magnificent specimen of the jeweller's art, dated 1721 His Majesty graciously accepted it and expressed himself much pleased with the gift

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST —The festival dinner of this hospital was held under the chairmanship of Alderman and Sheriff Sir George Wyatt Truscott at the Stationers' Hall, Ludgate hill, London, on May 20th In the course of replying to the toast of "The Medical Staff" Dr G A. Heron referred to the congress for discussing the means by which the spread of consumption may be prevented which is proposed to be held in Paris in October, 1904 A report would be made to that congress of what was being done in various countries by the working men's societies to assist in preventing the spread of that disease A request had been received by the authorities of the City of London Hospital asking that the English working men's friendly societies should supply [illegible] which they are taking [illegible] with a view to the facts [illegible] submitted to the congress [illegible] ble that the information required from the English working men's friendly societies should be supplied before the end of 1903 The chairman in proposing "Prosperity to the City of London Hospital for Diseases of the Chest," made an eloquent appeal for funds in aid of the institution He pointed out that the hospital was situated in a most densely populated area of the metropolis and explained what a terrible and dangerous thing it was to have a patient suffering from consumption living in a crowded and ill ventilated home He suggested that a very practi[illegible] free th[illegible] man's [illegible] ing to about £2000, a gratifying result which was received with much cheering Sir Edmund Hay Currie then proposed the toast of "The Committee and Executive Staff" and spoke of the admirable manner in which the administration of the hospital was carried on This toast was replied to by Sir Edward Sassoon, M P, treasurer and chairman of the hospital committee A long list of other toasts followed and it was not until a late hour that the company separated

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

IT is understood that on Friday, June 26th, the Earl of MEATH intends to draw the attention of the Government to the report of the Royal Commission on Physical Training in Scotland and to the report of the Inspector General of Recruiting for 1902 in the latter of which it is stated that the one subject which causes anxiety in the future as regards recruiting is the gradual deterioration of the physique of the working classes from which the bulk of the recruits must always be drawn He will also ask the Government what steps it proposes to take in order to arrest this physical deterioration "which varied and undoubted evidence shows to be gradually taking place amongst the poorer portions of the populations of the large cities of Great Britain and which if allowed to continue unchecked threatens the State with grave national peril"

HOUSE OF COMMONS

THURSDAY, MAY 21ST

Report on Enteric Fever and Dysentery

Dr Farquharson asked the Secretary of St[illegible]

Vivisection at University College

SIR FREDERICK BANBURY asked the Secretary of State for the Home Department what was the nat[illegible] graphs of the question I have already in previous answers given fully the main facts of the case As to the two last paragraphs Professor E H Starling performed the experiment referred to under Certificates B and E L

Leprosy in Ceylon

Mr SCHWANN asked the Secretary of State for the Colonies whether, in view of the prevalence of leprosy in Ceylon and of the fact that the ordinances recently passed by the Legislative Council provided for the compulsory segregation of lepers in Ceylon he would state what was the number of leper hospitals in Ceylon and how many leper patients [illegible], and whether he would consider the [illegible] for these people by the erection of [illegible] districts with a view to enable the [illegible] properly carried out if the present [illegible] —Mr CHAMBERLAIN replied There are two leper hospitals in Ceylon and 312 leper patients can be accommodated in them The leper ordinances do not require that lepers who can be otherwise properly isolated should be removed to a hospital and I am not aware that the hospital accommodation is insufficient but I will consult the Governor on the subject

MONDAY MAY 25TH

The Infected War Blankets

[illegible] May 4th

Sir THOMAS DEWAR asked the Secretary of State for War whether he [illegible] to is probably 30 000 of the same consignment in a warehouse in Assam street Whitechapel as they were found to contain the enteric fever bacilli in large numbers; and that the blanke[illegible] in both [illegible] as to disinfection in every case of infectious disease. I also issued special orders to South Africa two years ago neither to sell nor to send home any textile fabrics which might convey infection. I have caused the general officer commanding to investigate and to report fully on the matter and to take steps to have any condemned blankets still remaining in South Africa destroyed.

Nottingham Small-pox Hospital.

Mr. JOHN ELLIS asked the President of the Local Government Board whether his attention had been called to the erection by the corporation of Nottingham of a small pox hospital on the extreme northern boundary of its area in close proximity to a road along which numbers of persons were daily passing and to a number of dwelling-houses and a growing population; and whether he could take any steps in the matter for the protection of the public outside Nottingham.—Mr. LONG replied: The Nottingham Town Council has erected a small-pox hospital on a site which it considers the most suitable that could have been selected within the borough. I am informed that the neighbourhood is the most sparsely inhabited part of the borough, that there is no considerable population within a radius of two miles of the site, and that within this radius there are only a few scattered houses and the Bestwood colliery and ironworks, the latter being half a mile from the hospital. The town clerk informs me that the road referred to in the question is used almost solely by men working at the colliery and ironworks most of whom drive in breaks when going to and from work and have no need to pass at any other time. He adds that there is no evidence of any increase, or likelihood of increase, in the building operations in the neighbourhood. The town council has not applied to me for sanction to a loan in connexion with the hospital and I have no jurisdiction in the matter. I should gather that the conditions which the Local Government Board requires in the case of hospitals provided by means of loans sanctioned by it have been complied with, but I will make further inquiry as to this.

Medical Services in the Highlands.

Mr. CATHCART WASON asked the Lord Advocate if the committee of the Scottish Local Government Board which had been making inquiry into the subject of Poor law medical relief had also inquired into the grievances of the parochial medical officers in the highlands and islands of Scotland, and, if so, whether he would state what steps the Government proposed to take in the matter.—The LORD ADVOCATE replied: The *committee in question is a departmental one to inquire into and report* on the methods and conditions under which Poor-law medical relief is [illegible] Scotland an [illegible]. it is [illegible] thereto, [illegible] stri- [illegible] rom the l [illegible] cost of Poor-law medical relief and trained [illegible] and regulations for the management of poorhouses; and it is only incidentally, therefore, that the subject of the honourable Member's question can come within the terms of reference. In any case the committee not having reported it is not possible as yet to say what steps it may be the duty of the Government to take in the matter.

TUESDAY, MAY 26TH.

Plague at Hong-Kong.

Mr. WEIR asked the Secretary of State for the Colonies whether he was aware that 117 cases of plague resulting in 99 deaths were reported to have occurred at Hong-Kong in one week during the present month; and whether he would state when he proposed to lay upon the table of the House the reports of the medical and sanitary experts, Dr. W. J. R. Simpson and Mr. Robert Chadwick, who visited Hong-Kong last year in connexion with the plague.—Mr. CHAMBERLAIN replied: I am aware of the facts quoted by the hon. Member, which were reported to me by the governor in a telegram which was communicated to the press. I do not propose to lay the reports referred to on the table, but I have caused copies to be placed in the library.

BOOKS, ETC., RECEIVED.

WE[illegible] t Junior House [illegible] lodging, washing, and attendance.

WEST LONDON HOSPITAL, Hammersmith-road, W.—House Physician and House Surgeon, both for six months. Board and lodging provided.

Births, Marriages, and Deaths.

BIRTHS.

CHANNER.—On May 12th, at Park-hill, Ealing, W., the wife of [illegible] Channer, I.M.S., of a son.

[illegible] 63, Sackville-road, Hove, the wife [illegible] M. Cantab., of a daughter.

[illegible] roke-grove, W., the wife of C. E. [illegible] of a son.

MARRIAGES.

GRIMWADE—TANNER.—On 30th March, at St. Mary's, Caulfield, Victoria, by the Rev. A. H. J. Priest, assisted by the Rev. Canon Sutton, Alfred Sheppard Grimwade, M.R.C.S. Eng., L.R.C.P. Lond., third son of the Hon. F. S. Grimwade, Harleston, Caulfield, to Amy Gertrude, second daughter of Thomas Tanner, Esq., Old Trafford, Manchester, England.

MILLS—MACDOUGALL.—At 42, Millbrae-road, Langside, Glasgow, on the 21st inst., by the Rev. D. Georgeson, U.F. Church, Bowling, assisted by Rev. D. Taylor, U.F. Church, West Calder, Robert J. Mills, M.B., Ch.B. Glasg., Hirst, Morpeth, to Barbara Chisholm (Cissy), *eldest daughter of the late Wm. Macdougall, Charing* Cross, Glasgow.

RICE—SHENTON.—On April 18th, at Perth, West Australia, Hubert Richard Rice, M.R.C.S., L.R.C.P. Lond., to Florence Julia, third daughter of Sir George Shenton, President of the Legislative Council of West Australia, Crawley Park, Perth.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

CAN A VARICOCELE BE CAUSED BY A STRAIN?

To the Editors of THE LANCET.

SIRS,—During the last few weeks I have had two cases of the above complaint following the lifting of heavy weights and slipping of the foot. In the first case (a boy aged 14) nothing ailed the patient before the accident, on the occurrence of which he was obliged to leave his work in the pit owing to pain and swelling in the left inguinal region. The swelling was above the size of a pigeon's egg and under rest and warm applications it subsided in about five days leaving well-marked varicocele. In the second case there was a predisposition to varicocele; following the strain there was also a sudden darting pain from the loin to the left testis and incapacity from following his employment. One of these cases has already come under the arbitrator's hands (under the Compensation Act) and is still undecided, the chief defence against the claim being that "an accident is not mentioned in the leading text-books as being the cause of varicocele." I should be glad of some enlightenment on the point.

I am, Sirs, yours faithfully,
ENQUIRER.

⁂ There is nothing intrinsically impossible in a great straining giving rise to a varicocele. It is not, however, a common cause, but anything which produces excessive pressure in the intra-abdominal portion of the spermatic veins may overcome the valves and so bring about dilatation of the pampiniform plexus.—ED. L.

A QUESTION OF NOMENCLATURE.

To the Editors of THE LANCET.

SIRS,—In the "Mirror of Hospital Practice" in THE LANCET of May 23rd, p. 1444, two very interesting cases under Sir W. J. Collins's care are reported at length under the name of "Richter's Hernia." Should it not be *Littré's hernia?* I believe Littré was the first to describe partial inclusion of the intestinal lumen in a hernial sac as a cause of intestinal obstruction and that this particular condition has up to the present been usually termed "Littré's hernia." If any of your correspondents can inform me I shall personally be glad and I feel sure that candidates for the Fellowship will be glad of a reduction in the number of conditions and operations associated with a name, however renowned, instead of a descriptive adjective, referring anatomically or pathologically to the position or causation of the lesion.

I am, Sirs, yours faithfully,
May 25th, 1903. M.D.

⁂ We publish our correspondent's letter, but the point that he raises was discussed in an annotation which appeared at p. 1460 of THE LANCET of May 23rd, and which he appears to have overlooked.—ED. L.

DANIEL LAMBERT'S CLOTHES.

ACCORDING to the *Westminster Gazette*, at an auction sale recently held at the London Inn, Stamford, the clothes of Daniel Lambert, the famous eighteenth-century giant, were offered to the bidders, together with those of Tom Thumb, which were left at the hotel by the dwarf as a contrast. The articles have long been, after Burleigh House, the chief attraction of Stamford Town in the eyes of many Lincolnshire county people. Lambert, who weighed 53 stones, died at Stamford in June, 1809. The sum of £75 was offered for the clothes, but the lot was withdrawn.

"ONLY HAVE FAITH."

ON May 16th we reprinted a Christian Scientist handbill which promised "No more death" to those who "Only have faith." The following story is given by a reviewer in the *Daily Express*:—

> A woman who went to a Christian Science physician and told him that her husband was ill received this assurance: "Tut, tut; your husband is not ill but only thinks he is. Tell him so and come back and inform me next Tuesday week how he is getting on."
>
> On the following Tuesday week the distracted wife called upon the Christian Scientist.
>
> "Well," inquired the faith healer, "and how is your husband now?"
>
> "He is all right; there is nothing whatever the matter with him," she replied. "The only trouble is that he thinks he is dead, and the undertaker thought so too, for he buried him yesterday."

THE "DIAMOND CIGAR."

THE "diamond cigar" presents a distinct novelty as regards shape, which is considered to prevent the concentration of tarry matters and nicotine at the mouth end of the cigar when smoked. Of course, it is well-known that the products of the destructive distillation of the leaf are apt to collect at the mouth end of the cigar as smoking progresses. In order to avoid this accumulation of the nicotine and moisture the diamond cigar is constructed in the following way. A strip of special Havana tobacco runs through the entire length of the cigar and is surrounded by a short bundle of various Havana tobaccos which form the body of the cigar. The whole is inclosed in a wrapper or outer leaf. The shape of the cigar is thus similar to that of an elongated cork float used in fishing, the two ends being of about the diameter of a cigarette and about an inch long, while the size of the central section is the same as that of an ordinary cigar. The result is that the nicotine and tarry compounds collect at the end of the short bundle and not so much at the tip of the cigar. A practical trial certainly supported this view to some extent, the mouth end being dry and comparatively free from tarry matters when the cigar was finished. These cigars are obtainable from Messrs. Henry Welfare and Co. of 30, Clapham-road, London, S.W.

"THE GREAT PHYSICIAN."

WE have received from Herr Nicolaus Lehmann of Prague a photogravure of a picture bearing the above title by the well-known artist Gabriel Von Max. The picture represents the Saviour sitting at the couch of the daughter of Jairus. Our Lord is holding the girl's right hand, and the artist has very well expressed the gradual awakening from the sleep of death which the touch of the Divine Humanity imparts. The size of the reproduction is 47 by 69 centimetres, the price being £1 10*s*. It is a very dignified and simple conception of a striking incident.

THE KIN-HEE QUICK POT.

THIS tea or coffee pot, for it may be used for either purpose, has the merit of simplicity. It consists of two containers, the upper one, the infusing pot, being inverted and fitting into the lower one. The infusion of coffee or tea is made in the upper container or infuser which is detached for the purpose. When it is considered that the tea or coffee has been sufficiently infused the lower container which is fitted with a spout and handle is pressed firmly into the top of the infusing pot. The whole apparatus is then inverted so that the infusing pot is at the top and the container below. By means of a valve at the top of the infusing pot air is allowed to enter and the infusion then passes through a cloth strainer into the lower pot. Both infusion and percolation are thus effected. The result is excellent in regard to making either tea or coffee by this method. The time of infusion is under absolute control, there is no loss of fragrance or aroma, and the injurious astringent matters may be rejected. This principle in the making of both tea and coffee is physiologically correct. A specimen Kin-Hee pot in white metal was submitted to us for inspection and trial by Kin-Hee, Limited, 6 and 8, Eastcheap.

U. R.—The most comprehensive work on the chemistry of the urine is Neubauer and Vogel's "Harnanalyse"; the last German edition was published by Kreidel in Wiesbaden in 1898, two volumes, price about 22*s*. It could be obtained through foreign booksellers such as Messrs. Williams and Norgate, Henrietta-street, Covent-garden, London, W.C. The following can also be recommended:—"Practical Uranalysis and Urinary Diagnosis," by Charles W. Purdy, M.D.; pp. 392; Philadelphia, F. A. Davies Company; 1900. We understand that the publishers have no British agency so that the book would have to be ordered from America. "Clinical Examination of Urine, with an Atlas of Urinary Deposits," by Lindley Scott, M.D.; London, J. and A. Churchill; 1900. For picric acid testing the late Sir George Johnson's little book published in London about 15 years ago might be consulted. Clinical information will be found in "A Manual of Clinical Diagnosis," by Charles E. Simon; London, Henry Kimpton (13, Furnival-street, Holborn, E.C.); 1900.

Calomel.—Our correspondent would find the following books useful: Osler's "Principles and Practice of Medicine" (Kimpton); Judson Bury's "Clinical Medicine" (Griffin and Co.); Hares' "Therapeutics" (Henry Kimpton); "Clinical Psychiatry," translated by Dr. Defendorf (Macmillan and Co.); Mercer's "Psychology, Normal and Morbid" (Swan Sonnenschein); and Gowers's treatises on neurology. For special subjects Allbutt's "System of Medicine" may be consulted.

F. C. K.—The idea is not a new one, *vide* THE LANCET, vol. ii., 1871, p. 860, vol. i., 1875, p. 358, and vol. i., 1887, p. 894. We can see neither advantage nor disadvantage in the proposal.

M.B.—Calomel and starch.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor "

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager "*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C , are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager. Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris

An Address

ON

THE PERILS AND COMPLICATIONS OF FIBROIDS AFTER THE MENOPAUSE.

Delivered before the Wimbledon and District Medical Society on May 8th, 1903,

BY J. BLAND-SUTTON, F.R.C.S. ENG.,
SURGEON TO THE CHELSEA HOSPITAL FOR WOMEN; SURGEON TO OUT-PATIENTS AT THE MIDDLESEX HOSPITAL.

GENTLEMEN,—It was formerly taught and believed, even by thoughtful men, that uterine fibroids ceased to be troublesome with the cessation of menstruation. It is quite certain that a new chapter in their natural history requires to be written.

Uterine fibroids stand almost alone among tumours in the peculiarity of their age distribution, for they only arise during the menstrual period of life (from 15 to 45 years of age), but they stand absolutely alone among tumours in possessing another remarkable character. As a rule they cease to grow after the menopause and in some instances they undergo a marked diminution in size. Many writers are of opinion that they may even disappear. This must be a very exceptional phenomenon and hard to prove satisfactorily and upon which I have always entertained the gravest doubts.

The object of this communication is to discuss the complications of uterine fibroids after the menopause, for though, as a rule, they cease to grow after this event, they are frequently sources of great peril to life, not only in coexisting with other serious diseases of the uterus and ovaries, but the very fact that they are apt to diminish in size is in itself an occasional element of danger. Apart, however, from these conditions, the fibroids themselves are mainly sources of trouble on account of the degenerate and septic changes to which they are liable.

At the outset of this address it is essential to bear in mind that the presence of a fibroid in the uterus in a very large proportion of women has a very malicious influence in delaying the menopause. Many times I have removed fibroids from the uterus in patients between the fiftieth and sixtieth years of life in whom the monthly losses of blood were more profuse than at the age of 25 years. It is an important question whether the irregular and long maintained vaginal fluxes of blood in women with uterine fibroids after the fiftieth year of age should be regarded as menstruation in the proper acceptation of the term. On the other hand a woman may enter on the menopause at 42 or 45 years of age though a large fibroid may occupy the cavity of the uterus. In October, 1896, I removed from a woman, aged 45 years, a fibroid weighing 10 pounds sessile on the fundus of the uterus. She ceased to menstruate at the age of 42 years.[1] An early menopause under these conditions is about as rare as is a fibroid taking on rapid growth after the menopause. My earliest experience of this is very vivid in my mind, because it happened in the first patient on whom I performed hysterectomy with intraperitoneal treatment of the stump. The patient was a childless married woman, 48 years of age, who was known to have had a fibroid for nine years associated with metrorrhagia; in October, 1889, the catamenia ceased. Subsequently the tumour increased in size and became impacted in the pelvis and interfered with th [illegible]

18

st

in itself occasionally a source of danger, especially when pedunculated, for the tumour may be so big that its size prevents it from tumbling into the pelvis, but after the shrinking consequent on the menopause such a fibroid may fall into the true pelvis and become impacted. This, I admit, is a very rare complication, but it happens. In 1902 a patient, 55 years of age, who had her menopause at her forty-seventh year, was placed under my care in the Chelsea Hospital for Women for recurrent attacks of retention of urine due to a tumour of this kind. So long as the patient remained quiet she had no trouble, but a long walk, jolting in an omnibus, or running down stairs caused the tumour to fall into the true pelvis and to obstruct the urine; the patient would send for her medical attendant and he would push the tumour out of the pelvis and relieve the retention. At last the retention occurred so frequently that I was asked to remove the tumour; it was pedunculated, grew from the fundus of the uterus, and was equal in size to a turkey's egg and very hard. Since the operation she had remained free from retention of urine. Rare as complications of this kind undoubtedly are they are outdone on the score of rarity by the remarkable case recorded by Arnott. A maiden lady, aged 72 years, was knocked down by a large dog and fell forwards on the pavement; she died in 34 hours. At the necropsy a circular hole was found in a coil of ileum which lay between the anterior abdominal wall and a large calcified fibroid of the uterus.

Let us now deal with what I regard as the most frequent and the greatest danger connected with uterine fibroids after the menopause—viz., necrotic and septic changes. During the menstrual period of life fibroids generally possess an abundant supply of blood. In some instances they are so vascular that they are like huge cavernous angiomata, as those who have occasion to deal with them surgically know full well. In patients who retain their tumours till the menopause (and they are numerous) the cessation of menstruation is accompanied by a remarkable abatement in the blood-supply and the tumour ceases in many instances to grow, but the very fact that the nutritive irrigation, so to speak, of the tumour is arrested leads to degenerative changes and the fibroid becomes in many instances a dead sequestered body and so long as septic organisms are denied access it will remain inert; when from various causes putrefactive organisms gain access to these essentially dead tumours the results are often dire in the extreme.

It is far easier to prove that putrefactive organisms do obtain access to these dying or dead fibroids than to tell how they get to them. There is, however, one mode of access which to my mind is undeniable. The fibroids which give rise to most trouble after the menopause are the submucous variety and there seems a strong tendency when the uterus passes into its resting stage and the fibroid is shrinking and dying for the organ to attempt the extrusion of the tumour. A careful study of the cases which have come under my observation shows that in the majority of troublesome post-menopause fibroids a large proportion of them have undergone partial extrusion or the mouth of the uterus is widely dilated and renders the ingress of germs an easy matter. It is, of course, desirable to furnish some facts as to the relative frequency with which fibroids become necrotic and septic after the menopause. For this purpose there are some records available of an extremely valuable kind.

Recently Dr. C. J. Cullingworth has published a useful paper on the surgical treatment of uterine fibroids in which he has particularly analysed the conditions which rendered operative interference necessary and in some imperative. Among 100 consecutive cases of this kind distributed between the twenty-third and sixty-first years of life ten of the patients had attained the fiftieth year and onwards. The changes in the fibroids in these elderly women were in all instances necrotic or septic in character. Subsequently Mrs. Scharlieb reported an analysis of 100 consecutive cases, their ages ranging from 18 to 68 years, carried out on Dr. Cullingworth's lines. Seven of the patients were over 50 years old. Mr. C. J. Bond of Leicester published a consecutive series of 50 cases in which hysterectomy was performed for fibroids. Four of his patients were 50 years old and upwards. The oldest patient on the list is noteworthy. She was operated upon for a fibroid in her fifty-sixth year, but she had her menopause at 40 years.[3] Dr. Lionel Provis, registrar to the Chelsea Hospital for Women, at my suggestion, made a list of 100 consecutive cases of operation for fibroids treated in this institution by the staff generally. The results are instructive. The youngest patient was 25 years of age and the oldest was 66 years of age, and of this number 11 of the patients were aged 50 years and upwards. The distribution is as follows: from 25 to 29 years, five operations; from 30 to 39 years, 37 operations; from 40 to 49 years, 47 operations; and from 50 to 66 years, 11 operations. The oldest patient in this particular series was aged 66 years and she had a very large septic submucous fibroid which had to be removed piecemeal. In 1902 I performed hysterectomy on a woman, 69 years of age, for a very large septic fibroid and an incarcerated ovarian cyst. The peritoneum had been infected through the left Fallopian tube before the operation and the patient died.[4] My oldest patient was 73 years of age and I removed a mass of fibroid weighing 28 pounds with success. The operation, which took place at the Middlesex Hospital, was a necessity because the tumour had become so cumbersome that she could not rest in bed.[5]

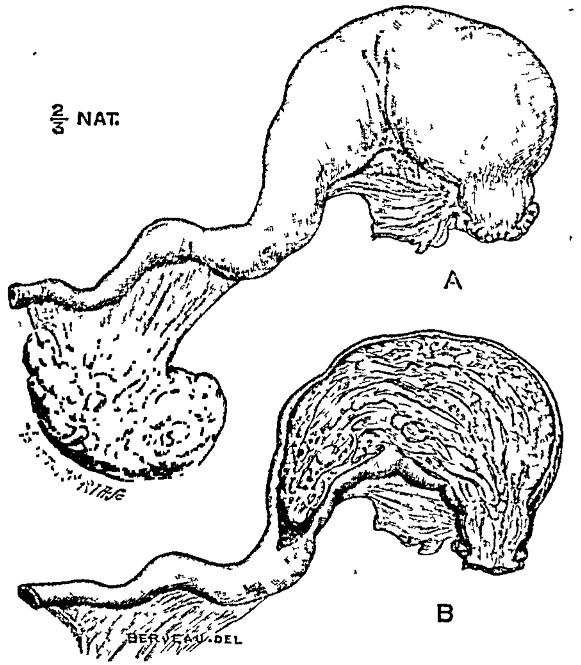
[3] THE LANCET, Jan. 17th, 1903, p. 162.

It will be clear to an impartial observer that even by fixing the menopause at the late age of 50 years uterine fibroids are very often sources of trouble, ill-health, and great peril to those who unfortunately possess them. One of the greatest perils which can happen to a woman with a fibroid in her uterus is to become pregnant, but after the forty-fifth year she is beset with a danger of quite another kind—namely, cancer of the endometrium. I have dealt with this serious subject so recently[6] that here I need only express it in the form of an aphorism. *When a woman with uterine fibroids has passed the menopause and begins to have irregular profuse uterine hæmorrhages it is extremely* probable that she has cancer of the body of the uterus. In a remarkable case of this kind under my care the patient had primary cancer of the Fallopian tube. Her case is fully recorded in the Transactions of the Obstetrical Society for 1902. She was a childless married woman, aged 57 years, and had her menopause at the age of 49 years. For many years she had suffered from what was regarded as a large fibroid tumour. Some months before coming under observation the patient complained of irregular, frequent, and rather abundant fluxes of blood from the vagina and this led me to suspect that the fibroid had become septic or that cancer had developed in the uterus. However, when an operation was performed I found the fibroid to be quite healthy, also the endometrium, but the ampulla of the left Fallopian tube contained a soft vascular tumour (*vide* illustration) which proved on microscopical examination to be a typical example of cancer and a portion of it had made its way through the cœlomic ostium of the tube and infected the peritoneum.



A. The ampulla of a Fallopian tube with cancer. B. The tube in section showing a portion of the cancer making its way through the cœlomic ostium.

The subject may be summarised for discussion something in this way. Fibroids only arise in the uterus during menstrual life—that is, from 15 to 45 years of age. As a rule they cease to grow after the menopause; after this event they may shrink. Some writers believe that they occasionally disappear, but this is very hard to prove and harder still to believe; therefore, as a concession to tradition, it may be described as a phenomenon about as rare as the advent of a comet. After the menopause fibroids sometimes grow and though an unusual condition it rests on the accurate observations of trained observers. Though a fibroid may cease to grow after the menopause it is still liable to extrusion from the uterus and gangrene with all its dangers and enmity to life.

Surely there is nothing in the whole range of surgery more ironical than a woman spending 20 or even 30 years of her life as a chronic invalid on account of a uterine fibroid in the expectation that at the menopause she will be restored to health and begin a new life and then to realise that far from this dream being fulfilled the fibroid becomes necrotic, extruded, or septic, and places her life in the gravest peril, and that she may die in spite of surgical intervention.

A Lecture

ON

MENTAL UNSOUNDNESS AMOUNTING TO CERTIFIABLE INSANITY AND ITS DIAGNOSIS.

Delivered at the Medical Graduates' College and Polyclinic on April 29th, 1903,

By ROBERT JONES, M.D., M.R.C.P. Lond., F.R.C.S. Eng.,

RESIDENT PHYSICIAN AND MEDICAL SUPERINTENDENT OF THE CLAYBURY ASYLUM.

Gentlemen,—The line of demarcation between sanity and insanity is an ill-defined one and the borderland province between the two is a narrow, uncertain, and variable territory. Its exact limitations are determined by the discretion and judgment of the certifying medical practitioner and the key of interpretation in this regard is in the hands of each one of you—who may be called upon at any time to use it. For the responsibility of this distinction heavy penalties—nay, even financial disaster—may be incurred, as in this country it is a serious matter to deprive an individual of his liberty and in an action of so serious an import the burden of proving insanity to the satisfaction of a non-expert British jury rests with the certifier. It is therefore well to remember that a medical man may be subject to an action at law on the part of any certified person who upon his discharge from the licensed house or asylum is entitled to a copy of the certificates and other documents upon which his alleged lunacy was based. Moreover, a medical man may be convicted of a misdemeanour if, in the words of the Act, he has made a wilful mis-statement in any medical or other certificate or in any statement or report of bodily or mental condition under the Act. It thus behoves every practitioner—even the youngest and most infallible—not only to exercise caution, vigilance, and due care in the recording of observations, the narrating of facts, and the deducing of conclusions necessary for the compilation of his certificate, but also that he should fortify himself with a sound—*I will not say* expert—knowledge of mental diseases so that he may with confidence discharge the responsibilities which the law imposes upon him in the practice of this branch of forensic medicine and thus be able to act with a readiness, accuracy, and precision which the possession of this knowledge implies.

Insanity has long since ceased to be looked upon as something mysterious or as a possession by evil spirits. It is nothing more or less than a disturbance of mind involving a disturbance of conduct—the former a sign and the latter a symptom of disturbed nerve processes. With every mental change it is probably without exception that some change occurs in the central nervous system. There is thus no mental state without its corresponding nervous state—"No psychosis without neurosis." What the relation and interdependence of mental to bodily condition may be is too explained and the principle of "psycho-physical parallelism" stands merely as a statement of fact and not as an explanation. To suggest or to imply causation on the material or on the immaterial side is unjustifiable. By the term "mind" I do not mean as ordinarily that mind connotes something spiritual or material which lies behind the particular manifestations of mental life—anything metaphysical or mysterious behind mental processes. I use the term "mind" to refer to the sum total of mental processes which are experienced during a lifetime and in its psychological sense to imply feelings, impulses, and ideas. Another term frequently referred to in the explication of mental diseases is "consciousness." In my remarks the term is taken to imply the sum total of mental processes which make up *present* experience—the actual NOW. An acquaintance with the elements of psychology affords considerable assistance to the student of mental problems, for it enables him to analyse concrete or actual mental experience into its simplest components, to discover how these combine and by what laws, and also to bring them into connexion with their physiological or bodily conditions.

[6] Clinical Journal, Oct. 23rd, 1901.

It is well known that the cerebral cortex is the most vascular tissue in the body and it is therefore natural to seek for important changes indicating insanity in the intricate nutritive plexus of the cerebral blood-vessels and the part of the brain mantle supplied by this plexus. The microscopic appearance of the brain after gross dementia seems to point out that the number and size of the cells in the second layer of the cortex vary in direct relation to the amount of dementia, and we may assume that the morbid anatomy of the cells of the forebrain—the prosencephalon—is closely connected with disturbances of mind. But hitherto pathology has not illumined the relationship of mind and matter nor has it enabled us to do more than merely assert that when there is brain disease there also is mental disease. We have no pathological classification of insanity, and, broadly but erroneously, we can only state that insanity is a symptom-complex which may be due to an inflammation of the brain and its membranes, to a brain injury, a brain defect, a malnutrition, or to a reflex disturbance, and that the symptom-complex is nothing more or less than an excess, a deficiency, or a perversion of normal mental processes. The pathology of insanity throws absolutely no light upon the pure and primary psychoses and no changes in the brain have been discovered or described as in any way characteristic of, or *corresponding to, the changes in consciousness* which are observed to occur, after death by chloroform or alcohol or after such drugs as strychnia, conium, morphia, &c., or in connexion with such diseases as tetanus, hydrophobia, &c., in which marked mental as well as physical symptoms are known to occur. Indeed, it is not improbable that many of the changes which have been described in the cortical cells as indications of insanity either represent gross dissociations of nerve molecules which may occur at the moment of death or [illegible] -estigator and [illegible] ces. The finer [illegible] are still sufficient to produce mental disturbance, remain undiscovered and up to the present we must remain content with such platitudes as that "the brain is the organ of mind," that it is "the mirror of the outer world" or more abstrusely and equally vague that "mind is force oscillating in the protoplasm of the cell," without in any way throwing light upon the nature of the parallelism which is our hypothesis. *The fact therefore remains that positive observation on* which to base a pathological classification of insanity is still a desideratum. As to a classification not based upon pathology, which is from a scientific point of view both arbitrary and artificial, there is consolation, if not satisfaction, that we have one based upon symptoms which, after all, is practical, which can meet the everyday requirements of the practising physician, and which is in the main what concerns us to-day.

At the present moment there are probably no less than 110,000 certified insane persons in England and Wales alone, of whom approximately about 50,000 are males and 60,000 are females. There are probably also for every certified male lunatic two other persons who, by heredity and predisposition, are on the borderland between sanity and insanity and from whose ranks are recruited the majority of cases of "occurring" insanity. According to the division of insane persons into private and pauper classes do patients require either two or one medical certificate for their detention, and as there are in England and Wales about 23,000 registered medical men and women each medical practitioner has the responsibility at his own door—if an average were taken—of having deprived at least four persons of their liberty and franchise. Not that this has been unnecessarily or unjustifiably effected. In all probability, nay, in all certitude, this deprivation of freedom has been both necessary and justifiable, not only for the good of the patient, the interest of his property, and the safety of his family, but also for that of society at large.

In order fully to estimate the import of mental unsoundness with a view to certification we have to bear in mind that the standard of mental health is a variable one and that not only have the symptoms presented by the individual to be considered but also his relation to the world in which he exists and in which he is maintained. In the brief time at my disposal I can do no more than merely hint at or indicate the varieties and degrees of mental unsoundness which may prove of assistance to the medical practitioner in his estimate of certifiable insanity and I will consider two points: firstly, what symptoms constitute mental unsoundness or insanity; and, secondly, the consideration of these symptoms so that we may be able to analyse the essential nature of the insanity of which the symptoms are but evidence.

In the latter analysis we shall consider not only the primary psychoses but also those forms of insanity which occur in association with the great neuroses—epilepsy, hysteria, and chorea—as well as those cases of dementia which fall to the lot of the neurologist and which are due to coarse formative lesions, such as are induced by neoplasms (specific, innocent, and malignant), parasites, special toxins, meningitis and those due to vascular changes, thrombosis, embolism, hæmorrhages, softening, sclerosis, &c. It is acknowledged that certain mental states have certain bodily conditions as almost invariable accompaniments and no inconsiderable assistance to diagnosis is obtained from these, to which we shall refer later.

Firstly, as to what constitutes mental unsoundness or insanity. Delusions have been considered both by the lay as well as the legal mind to be the essential characteristic, and although this departure from normal mental health often finds the readiest expression by the patient himself, and although also it offers the greatest superficial contrast between sanity and insanity, the presence of illusions, hallucinations, or delusions, although strong indications, are not absolute signs of insanity. *Joan of Arc, Peter* the Great, [illegible] od women [illegible] delusions [illegible], yet they have been able to carry out all or most of their particular duties in life.

In the development of the individual certain instincts deeply implanted in man's nature and characteristic of him are gradually evolved. These relate, firstly, to his own support, his search for food, his retention of animal heat, and his self-preservation by security from attack and his capacity for self-defence; and secondly, to his instinct of reproduction and the support and care of his young by means of which his species is perpetuated. In the course of his physical and mental growth certain reverses or checks are liable to occur to the instincts named, to his perception of the various impressions which reach him from the outer world, or to the power which he has of interpreting these impressions and associating them together. When these reversions or checks, acting through circumstances from *without or causes from* within, affect his perceptions or his interpretation of perceptions we have the cause of illusions and hallucinations and when they affect the power of discrimination—the power he has of using old facts in new circumstances by discerning their agreement or disagreement—we have arising hence the elements of delusions; indeed, one form of insanity—paranoia—is looked upon as a pure reversion—an anthropological degeneration in an atavistic sense to an ancestral type in which the mysterious forces or powers of nature are often personified to give an explanation of the delusions, the belief being entertained that nature in some occult way and with occult power acts upon the human organism.

In the discussion of insanity the standard of mental health is, as stated, a variable one, and what would indicate insanity in a person of previously high intellectual power and culture would not indicate insanity in members of a lower order or an inferior race. The beliefs which were creeds and in consonance with those of an early period of as a rule, higher and there is in the early stages an irritability in small matters, an apathy, or a peculiar abstraction, a forgetfulness or tendency to sleep and to be dull with a lack of will power in regard to important events and matters of business. The latter has often been communicated to me by the relatives as common in cases of general paralysis. Physical symptoms evinced by headache, tremor of facial muscles and tongue, of the speech and the handwriting, also occur, the knee-jerks are increased (or possibly in tabetic cases absent), and pupil phenomena (noted in the Argyll-Robertson reaction) confirm the diagnosis of general paralysis. Age has certain controlling influences as already stated. The mental condition of coarse brain lesions is that of dementia and it is accompanied by physical signs according to the locality affected. It is this form which is familiar to the neurologist.

The mental state in association with epilepsy is recognisable by the peculiarly dull appearance of the patient not unlike that of slight drunkenness or of alcoholism, but the delusions if present are religious and sexual. There is a record of previous fits, the symptoms come on suddenly, but there may be marked fury or excitement which is uncontrollable, or there may be a state of more or less prolonged, dreamy, dull consciousness described by Crichton Browne. The mental condition associated with hysteria is of a superficial, changeable, and emotional character with a tendency to foolish mendacity and sexual ideas. That associated with chorea may in pregnant women be of very serious import. As a rule mild dementia accompanies chorea more often than mania or melancholia. Almost all alcoholic forms are characterised by the presence of hallucinations, which are often visual and mostly terrifying, by the presence of fixed delusions of a persecutory nature such as those of poisoning or mutilation; there is also marked amnesia of a special kind. The tremors, absent knee-jerks, and frequent morning sickness may help diagnosis in respect of alcoholic insanity. In some cases of mania there is a prodromal period of depression which is not easy to diagnose from primary dementia, only that explosions usually follow in mania and loss of memory in dementia.

In cases presenting motor excitement it is necessary to determine whether this be due to epilepsy, simple mania, or the maniacal phases of general paralysis. As general paralysis occurs in from 12 to 20 per cent. of all cases of insanity and as it is a disease of mature adult male life and one in which syphilis is a precursor, as also it is one in which dangerous excitement occurs and there is lavish prodigality of means and the disease is incurable, it is necessary to form an early and accurate diagnosis so that removal under care may be effected. It is best for the patient that he should linger out his days in a comparatively felicitous existence, unconscious of his fatal malady, such as may be secured in an asylum.

In conclusion, therefore, when a case of mental unsoundness as defined by our hypothesis is presented to us, we have to consider the import of delusions not only as to their content but also as to their systematisation, the question of psychical weakness in the abstract, abnormal irritability, defect or perversion of will power, and changes in the emotional states; confident that we are doing right by the patient in sequestrating him from managing himself or his affairs if he is suffering from the acute form of any variety of insanity, for all such are potential suicides—if he is suffering from confirmed systematised delusions of a persecutory character, for all such paranoiacs are potential homicides—if he is suffering from the early symptoms of general paralysis or if there are great violence, noise, excitement, and sexual trouble—and that we are doing right by not certifying if the insanity is in a young person of either sex, is due to toxins, or is of a mild or subacute and temporary variety.

Claybury Asylum, Woodford.

THE ROYAL NAVAL NURSING SERVICE.—On Friday, May 29th, Her Majesty the Queen presented badges to two head sisters and 22 nursing sisters of Queen Alexandra's Royal Naval Nursing Service at Buckingham Palace. Rear-Admiral John Durnford, C.B., D.S.O., a Naval Lord of the Admiralty, Inspector-General Sir Henry F. Norbury, K.C.B., K.H.S., R.N., Director-General of the Medical Department, and Staff Surgeon W. J. Colborne, R.N., Assistant to the Director-General, also attended and had the honour of being presented to Her Majesty.

Clinical Remarks

ON

THE TREATMENT OF GANGRENOUS HERNIÆ BY ENTERECTOMY.[1]

Delivered at University College Hospital in February, 1903,

BY ARTHUR E. BARKER, F.R.C.S. ENG.,
PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY AT UNIVERSITY COLLEGE AND SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—Some time ago I gave you a few facts as to the results obtained in this hospital from the treatment of strangulated hernia, either by taxis or operation, in 406 consecutive cases (*vide* THE LANCET, May 30th, p. 1495). Certain conclusions seemed justifiable from this study, and above all that the mode of dealing with gangrenous hernia hitherto adopted appears to require modification at the present day. The question what to do in a case of gangrenous hernia is one the seriousness of which is well known to all surgeons of experience, and the factors which make such a case grave are also now fairly well recognised. They have been worked out by the anatomist, the bacteriologist, and the pathological chemist. In a given case, say, of gangrenous femoral hernia we have the following elements of danger: (1) the gut is destroyed by necrosis over a greater or less surface and therefore it cannot be returned into the abdomen; (2) the dead portion is septic in the highest degree; (3) the fluid of the sac, if there be any, is highly septic and may run back into the abdomen and infect it if the constriction has been divided before the sac has been well cleansed; and (4) the condition of things within the abdomen is also fraught with risk. Here the gut above the constriction is loaded with retained fæcal matter which is virulent in proportion to the time it has been pent up in a stagnant condition. The bowel is distended by this fluid, often to an enormous extent, and it is paralysed owing to causes unnecessary to trace for the present. But not only is it distended and paralysed but its structure is in many cases much altered. Its mucous membrane is inflamed, or even ulcerated (*vide* Case 3 below), from the point obstructed upwards, *often for some feet.* The submucosa and muscular coat are œdematous and the serous covering is sodden and discoloured from extravasation of blood; it may also be flecked with patches of lymph either on its free surface or in its subserous layers. In this condition it is now well known that the bowel, although its continuity is unbroken, can no longer offer much resistance to the passage through its walls of septic organisms and sooner or later these transude and set up a septic peritonitis. This has been long known of the bowel caught in the sac. But it is now clear that the same infection will take place sooner or later within the abdomen from the unbroken bowel above the constriction if the evacuation of the retained fermenting fæces be not provided for. Probably a certain amount of toxic exudation from the obstructed bowel is tolerated by the peritoneum as long as it is sound and is removed by its lymphatics, but the time comes when it is not removed and peritonitis is set up.

But beside these dangers the patient has probably been exhausted by vomiting and inadequate feeding for days. The vomited matter has been foul and in many cases it has been inhaled in fluid or vapour form into the lungs with more or less damage to them. *Moreover*, the patient has been confined to the recumbent position and the bases of the lungs may have been imperfectly expanded owing to the position and the painful condition in the abdomen and so have become œdematous, rendering them particularly vulnerable to infection. Again, the toxins stored up in the bowel above the constriction are absorbed and exert a depressing effect upon the whole economy.

Now it is in these retained contents of the bowel above the constriction and in their local and general toxic effects that the main danger of strangulation with or without mortification lies. Their irritating properties have been known ever since the artificial anus has been made for their evacuation in gangrenous hernia. The rapid production of excoriation or even ulceration of the skin around such an opening bears witness to their acrid nature. Again, the facts so often noted in former times when herniæ were more frequently reduced by taxis alone than now point in the same direction. We have all seen many such cases attacked after reduction by severe diarrhœa with blood-stained stools and other evidence of acute enteritis often terminating in death. The cause here has been explained to be the rapid rush of the pent-up toxic fluid into the empty and starved intestine below the constriction, setting up there an acute inflammation continuous with the inflamed and sodden tract above. Again, how often have we seen in the days of frequent taxis a patient die from peritonitis starting from the sodden but still unperforated loop returned into the abdomen or from pneumonia combined with moderate enteritis or peritonitis (*vide* Table II.[2]). But in addition to all this the bacteriological examinations of the fluids retained above the constriction made within the last few years by a number of observers have amply demonstrated its virulence and the chemical analyses its toxicity. Cushing's bacteriological studies on the swarming life found in the first discharge from an artificial anus for gangrene and the gradual disappearance of the bacteria as evacuation of the contents proceeded show this most fully.

---

[1] We have thought it best to publish this lecture in immediate sequence to that published last week, as though delivered at some distance of time apart the two are practically different portions of the same subject.—ED. L.

Now all this and the bad results of the earlier *primary* resections for gangrene have gradually led to the conclusion held by the majority of surgeons at the present day, that, in the words of Cushing, quoted here as one of the most recent and thoughtful writers on the subject and one of the most progressive surgeons, "If the gut is not viable experience has shown that the immediate establishment of an intestinal fistula is much the safest procedure, as this permits the immediate escape of the retained toxic products from the proximal bowel." Again, lower down: "Occasions doubtless arise when an immediate anastomosis can be made, but under ordinary circumstances I believe it is preferable, as stated above, to establish an artificial anus and allow all the contents of the bowel to be rapidly evacuated." But that the ultimate result in such cases is not generally good even in his hands may be inferred from the following lines in the same publication: "The cases with gangrenous bowel present a more difficult problem. With only two or three exceptions at this hospital (the Johns Hopkins) such conditions have led to a fatal termination. On one occasion Dr. Bloodgood resected and sutured a gangrenous bowel in a young man under general anæsthesia with recovery." The experience at University College Hospital bears out this statement. I find that in a series of years reaching down to date out of 20 consecutive cases of the formation of an artificial anus for gangrene only two ultimately recovered.

But in spite of this dismal experience the rule is still followed to day by most surgeons that in cases of gangrene of the gut the safest thing to do is to make an artificial anus. And yet notwithstanding the wide acceptance of this rule I venture to think that the time has come for its modification. My own experience based upon the last ten or 12 cases of gangrenous or greatly damaged intestine which I have had to treat has forced me to the conclusion that this rule, however sound in the past perhaps, is not so applicable at the present day.

Let me define my position a little more clearly. It seems to me that for those cases of gangrenous bowel in broken-down individuals who have been neglected or badly treated and who come to us almost moribund the rule must still hold good. Any long operation, and above all any prolonged general anæsthesia, will almost certainly be followed by death. The formation of an artificial anus, on the other hand, in these cases is easily and rapidly done under local anæsthesia and offers the patients the best if slender chance of recovery.

But in those instances in which our patients reach us in tolerably good *general* condition, although the state of the intestine is hopeless, I venture to think that a *wide-reaching* resection of the bowel offers the best prospect of recovery. Such cases come to us nowadays, I think, as a matter of observation in relatively greater numbers. The delay on the part of the public is less in seeking operative aid, and the pernicious practice of drenching these patients day after day with purgatives is less widespread than formerly. The previous treatment before they are handed over to the surgeon may still be dilatory, but it is more usual now to find that such cases have been placed under opium and the application of ice with occasional attempts at taxis. But, at any rate, they have been spared the constant forcing of the bowel under [illegible] quently increased [illegible] local condition of [illegible] more frequently in a better *general* state than formerly. This, at least, is my experience in a fairly large number of cases. And it has led me to the following conclusions.

1. The most imminent danger to the patient with a greatly damaged or actually gangrenous loop of intestine *lies in the condition of the bowel for the three or four feet above the constriction.* If this is simply put back or an artificial anus made the risks are enormous. In either case it only *slowly* relieves itself, in the first instance by passing on its toxic contents into healthy bowel below, there to be more or less absorbed with the further production of enteritis and toxæmia, and in the last by slowly discharging on the surface of the body. It must not be forgotten that this evacuation will be *slow*, for the distended and sodden bowel is in a state of paralysis often for days after the relief is given. In the meantime the patient is on his back with all the risks of pneumonia, toxæmia, and peritonitis.

2. In a case where the patient is in a reasonably good condition I cannot help thinking that to excise this dangerous portion of paralysed and sodden or ulcerated gut *en bloc* together with all its virulent contents is relatively the safest course. At one sweep the three or four feet of gut with pints of toxic material can be cleanly removed. And, moreover, by dividing the gut high up we get a portion less widely dilated and therefore more easily adapted to the contracted lower tube. But this last is not the crux of the situation, for of course we might make a lateral anastomosis. The great point is to remove at once *the contents as well as the diseased bowel* and to make our suture junction in relatively sound and clean gut. It may be objected that this demands a large and long operation and consequently a great strain on a feeble patient. But this is only relatively true in these days of improved technique and is balanced, I think, by the enormous gain to the patient of having a veritable "cesspool" removed from the abdomen cleanly and with it most of the really damaged and dangerous bowel, leaving the part above where there is less paresis or none and where our stitches will hold in sound tissue. But the excision *must be wide.* On this point we need have but little misgiving as far as the general nutrition of the body is concerned. It was pointed out years ago by Senn that in dogs at least one-third of the whole intestinal tract may be removed without any damage to the economy. Since then, in many cases six, seven, or even eight feet of the human small intestine have been removed successfully and without any injury to the general health.[3] If this be so and if, as I venture to think—indeed, it is almost certain—that the risks of gangrene of the intestine depend upon the conditions not only in the dead loop but in the three or four feet of gut above the point of constriction, there need be no hesitation on the ground of doubts as to the general future nutrition in removing any length of intestine up to some six or seven feet. Further, it may be pointed out that in only one particular does it take longer to excise six feet than it does to remove six inches. This is in the treatment of the divided mesentery. But I think that I can demonstrate a method by which the latter can be dealt with rapidly and effectively. Of course, the anastomosis of the actual ends can be made as quickly when several feet have been removed as when only a few inches have been resected and (if the respective lumina are in the former case more alike in size) even more rapidly.

The first case in which the above line of reasoning appeared to lead me to a successful result may now be mentioned briefly as it has already been fully recorded.[4]

CASE 1.—A young man, aged 20 years, was admitted into University College Hospital in July, 1899, for an inguinal hernia of moderate size but distinctly gangrenous after four [illegible] Instead of making an artificial anus [illegible] anastomosis I [illegible] healthy bowel [illegible] stitched, the bowel was divided, and the nearly equal lumina were anastomosed end to end (method described below). A radical cure by Bassini's method followed at once. Recovery was uneventful. The portion of gut removed measured three feet.

[4] Brit. Med. Jour., Dec. 23rd, 1899.

CASE 2.—The next case[5] was that of a woman, aged 46 years, with a gangrenous femoral hernia of three days' standing. Here the procedure was the same, but only one and a half feet were removed and the sac was drained with gauze for a few days. Recovery was without a hitch.

CASE 3.—The third case[6] was still more to the point and convinced me that extensive tracts of small intestine can be rapidly removed with no more shock to patients than short. And further, that with the removal of the over-filled, engorged, and ulcerated proximal loop, one of the great dangers was at once eliminated which are so potent in such cases. The patient, a feeble woman, aged 76 years, was admitted into University College Hospital on Jan. 10th, 1901. For two years she had had a large ventral hernia in the scar of an ovariotomy performed 30 years before—in 1870. On Jan. 8th and 9th she had not felt well and had had pain in the abdomen but no sickness. At 10 A.M. on the 10th the patient was seized with severe pain in the abdomen and vomited bile-stained fluid. The large tumour was swollen and tender; no more flatus was passed and she became faint. Later in the day she had another attack of faintness and sickness and brought up undigested bacon. Her state on admission is thus described in the hospital notes: "Feeble woman with intermittent pulse of 108; face pinched, tongue moist; condition but for age good." At 10 P.M. I operated and on opening the thin scar about one pint of dark, evil-smelling fluid gushed out of the sac. About three feet of strangulated gut were then found constricted by a strand of omentum at the neck of the sac. It had not quite lost its lustre but it was very black, foul, and distended with sanious fluid and its recovery seemed hopeless. I at once measured off with my fingers what was roughly estimated as about six feet (really it turned out to be five feet six inches). At all events I ran it through my fingers until a part was reached above which seemed to be sound enough to retain sutures and to furnish healthy plastic lymph. The mesentery was then clamped and sutured (see below) and the bowel was cut away from it. End-to-end anastomosis by suture followed and the abdomen was closed. The junction was completed in 44 minutes after the beginning of the operation. The last stitch closing the abdomen was finished within 63 minutes from the first cut. There was no shock, a very remarkable fact in the case of such a feeble old woman, and the patient was induced to sit up the next day and afterwards, and as a rule, only to lie down for sleep. I had her placed in an armchair by the fireside on the sixth day. The wound was found to be perfectly healed at the first dressing on the tenth day. Except for a trace of bronchitis and a little diarrhœa from the fourth to the seventh day recovery was uneventful. She presented herself at the hospital more than a year after operation in the best of health.

The surgical registrar's report on the parts removed is specially interesting here.

Five and a half feet of small intestine: three inches from the lower end is the seat of the distal constriction. The gut at this spot becomes intensely congested and hæmorrhagic, of a purple-black colour, and its walls are thickened with intense œdema. At the time of the operation there was a definite groove at this spot which has now disappeared after lying in weak spirit for 12 hours. On tracing the gut upwards from this point the first three feet are all intensely congested, the changes become less marked above, now only pale and œdematous, were operation. There is no groove or sudden change in the pathological appearances to mark the seat of any constriction of the proximal loop of gut, the congestion and œdema becoming gradually less when followed up the gut. On slitting up the gut the mucous membrane of the lowest three feet has a deep purple-black colour and the valvulæ conniventes are so swollen, discoloured, and pulpy-looking that it is difficult to say whether any ulceration exists. After lying some days in weak formalin the parts merely congested became paler and revealed three large patches in the last 18 inches of the gut where the mucosa was hæmorrhagic, partly gangrenous, and superficially eroded. Each patch involved the whole circumference for about three inches and the lowest, where the changes were most marked, had a definite abrupt linear border marking the seat of the distal constriction. In the next foot of the gut above there were two similar but smaller patches of mucous hæmorrhage and erosion only involving a part of the circumference of the bowel for about one inch by half an inch.

This condition of the bowel confirmed my belief that had it been returned into the abdomen whether *with* or *without* the formation of an artificial anus and with all its acrid contents which had already fouled the effusion in the sac nothing could have saved the patient. My only doubt for some days was whether I had removed enough of the bowel to secure a sound material capable of reparative energy for the anastomosis. But, at all events, the whole of the ulcerated portion with the large quantity of toxic material both within its lumen and infiltrating its walls had been removed and there was no evidence in the after history, except a little diarrhœa, that any dangerous amount had been left behind.

If anything was needed to strengthen the conclusion that the removal of large tracts of intestine above a gangrenous portion is desirable it appeared to be furnished by this case, and the absence of shock, even in so old and feeble a woman, seemed to prove that the removal of so much gut is not *necessarily* a severe strain, even upon a feeble patient.

In another recent successful case of a similar kind now to be briefly recorded I had, looking back at the last, no hesitation as to the course to be pursued.

CASE 4.—A woman, aged 52 years, was admitted into University College Hospital on Feb. 7th, 1903, at 1.30 A.M. with a left femoral hernia strangulated since the previous Monday (Feb. 2nd). There had been stercoraceous vomiting for the last two days. The patient was placid and in fair condition. The pulse was 72 and the temperature was 99° F. Coils of greatly distended intestine could be seen moving under the abdominal walls. After washing out the stomach and administration of chloroform lightly the sac was opened, the gut drawn down, and the constricted part found to be grey and gangrenous; in fact, it leaked on being handled and the destruction of the two inner coats could be felt between the finger and thumb. Both limbs of the coil were tied firmly above the constricted portion and the loop was cut away. With the threads used thus a strip of sterile gauze was tied over the cut ends previously well washed with normal saline solution. The abdomen was then opened in the middle line and the proximal and distal limbs were caught in the fingers and drawn from the neck of the sac and out of the abdominal wound followed by the gauze. The proximal loop of the bowel, measuring about two inches in diameter, was very largely distended with dark fluid and deeply congested for several feet. The mesentery was clamped (see below) and ligatured close to the bowel which was then cut away from it to the extent of over six feet with all its foul contents. (Be it remembered that a cylindrical tube two inches across will contain for every foot over one pint.) End-to-end anastomosis was then attempted, as in the other cases, but when nearly completed was found to be unsound owing to the difference of calibre. The portion sutured was therefore cut away and a lateral anastomosis was made higher up and the abdomen closed. The femoral wound was then sutured in the usual way. All this consumed more time (two and a quarter hours) than I like to think of—just double the time spent over the last operation mentioned above. But as the procedure included two enterectomies and a femoral herniotomy and was complicated by a tendency to bleed from the mesentery this is not so surprising. There was no shock and recovery was uneventful except for 13 loose stools within the first week and a little discharge from the femoral wound and from one stitch in the abdominal incision.

I should now like to sketch in outline the procedure I have adopted in these and the last five or six cases.[7] It differs in many respects from those which are commonly described and aims at saving time, securing accuracy of adjustment, and the elimination of undue manipulation with possibly tainted fingers.

When the gangrenous or extensively damaged loop has been drawn well out of the abdominal cavity, as in the last two cases, as far as the points to be divided the wound is packed with one end of a long roll of sterilised gauze, none of which can thereby be lost in the abdomen.

The first point, then, is to select the spot at which the distal and proximal ends of the damaged loop are to be divided, the first some two or three inches below the constriction and the other at any distance above it up to six or seven feet which may be considered to have reached sound bowel. Here the two portions are placed accurately side by side in their long axes and are clamped together firmly with one (first) pair of Doyen's forceps. Next the damaged loop is stretched to its full length so that each half of the mesentery is evenly applied to the other half. The two halves of this structure are then firmly clamped together with a second Doyen's forceps placed parallel to, and about one inch from, the bowel (Fig 1) Another Doyen's forceps is now made to close on the rest of the two leaves of the mesentery if it is too long to be included in one pair. The forceps can start from the point of the second pair, one blade being pushed through the two folds of the mesentery, and should close the latter up to the point at which the two limbs are held together in the first pair used to keep the two limbs of the gut together This latter pair if now removed and is placed only on the distal portion at the same spot (Fig. 2) Another is placed about half an inch more distally and between the two the gut, previously packed with gauze, is divided. The whole of the bowel still closed by forceps is now cut away from the mesentery round to the point opposite the forceps on the distal limb (Fig 2). The piece of bowel thus freed at one end and in its whole length is left hanging out of the abdomen over the edge of the table (Fig. 2) into a basin and then the forceps closing its end is removed, allowing the contents to escape into the basin and *draining the bowel both outside and inside the abdomen.* While the latter process is going on the two halves of the mesentery are stitched together laterally by strong threads passed through them from side to side between the clamps and the cut edges, all being tied on one side and including about two-thirds of an inch of mesentery in each ligature (Fig. 2) This closes the hole in the mesentery and at the same time the vessels going to the edges cut away from the bowel. All this time the contents of the bowel are running off into the basin on the floor. The anastomosis now remains to be made. But before the junction is begun the distended gut within the abdomen can be further unloaded by pressure on the abdominal walls and by drawing the coils if necessary through the fingers with a kind of "milking" action until their contents flow off into the basin below. The advantage of thus unloading the bowel cannot be overrated, and though I did not carry it out in the last case exactly as described I had so planned it for some time

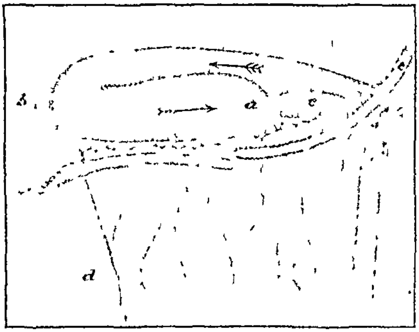
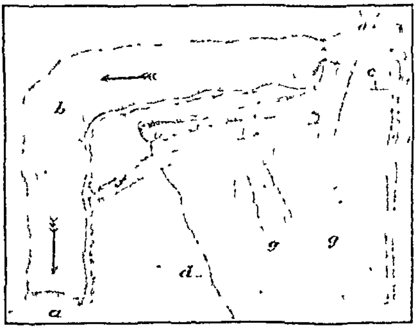
FIG. 1.



a, Constriction *b*, Proximal distended gut. *c*, Distal contracted gut *d*, Mesentery. *e*, Doyen's clamp on both loops *f*, Doyen's clamp on mesentery. The folded loop here represented is for convenience of drawing only a short one.

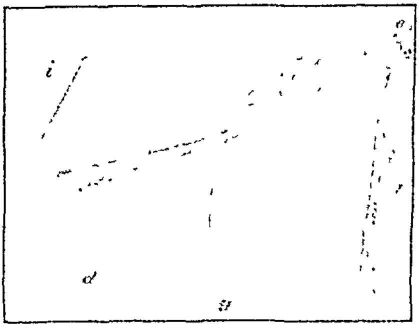
FIG. 2



a, Constriction supposed to be open in a basin on the floor *b*, Proximal distended limb going to basin. *c*, Distal limb clamped. *d*, Mesentery partly tied off. *e*, Doyen's clamp closing distal limb *f*, Doyen's clamp holding folded mesentery. *g*, Threads tying both layers of mesentery.

The junction of the two ends was done in all my last cases as follows. The clamped distal portion and the unclamped proximal, now empty and more or less reduced in size, were laid side by side in such a position that while their attached mesenteric margins corresponded at one point the axes of the two portions crossed one another obliquely. When now both were included in one pair of Doyen's forceps at the point at which their mesenteric borders crossed, their free margins also corresponded by the greater obliquity of the smaller bowel. In other words, when they came to be cut off flush with this forceps more was cut away from the free margin of the smaller bowel than from the proximal tube (Fig 3) which was divided only a little obliquely.

FIG. 3



a Of previous figure has been cut away. *b*, Proximal distended limb *c*, Distal limb clamped obliquely to latter. *d*, Mesentery stitched and cut from bowel *e*, Clamp holding two limbs together. *g*, Tail thread of suture uniting ends through all coats *i*, Sewing needle and thread *in situ* closing part of cut ends

The two tubes thus held together side by side in one forceps are again clamped nearer the abdomen by another pair as close as possible to the first and then being carefully packed with sterile gauze are cut with a knife or scissors flush with the *distal edge* of the first pair of forceps. The freed long coil of intestine and the stump of the distal end held in the forceps applied earlier in the operation now drop off and the gauze packing is changed. Then the forceps at the edges of the approximated tubes is removed, the second pair being left on with the cut edges previously clamped in the first projecting about a third of an inch beyond it (*Fig.* 3).

Now commencing at the mesenteric border, the adjacent edges of the two tubes are stitched together with a continuous suture, taking up *all* their coats until the free margins are reached Here the corner is turned and the opposite edges are similarly stitched until the suture reaches the mesenteric margins again and can be tied with the tail thread at the starting point (*Fig.* 3, *g*). Another forceps is then made to clamp both tubes three or four inches nearer the abdomen and the forceps holding them together for the first row of suturing is taken off. This enables the operator to place another line of continuous suture over the first and *folding it in.* This second row should, of course, take up only the serous, muscular, and fascial layer under the latter, avoiding the mucosa. When this has been carried quite round the bowel and has been tied to the tail thread at the starting point on the mesentery the anastomosis is complete and the forceps higher up is removed. The whole area of operation is now washed with sterile saline solution, especially the anastomosed portion of gut. The latter is then replaced in good position in the abdomen and this is closed with sutures. A pint of normal saline solution may be injected under the skin of the arm towards the axilla and five minims of solution of strychnine hypodermically. All other means for keeping up the patient's vitality, such as warmth and a rectal injection of brandy, are, of course, followed. And besides this I have long made it a practice to encourage such patients to spend all their waking hours in the sitting posture and only to lie down for sleep. This helps in preventing hypostatic pneumonia, as also probably does an occasional thorough rubbing over the back and bases of the lungs. In my oldest patient, aged 76 years, it has been mentioned that she was lifted out of bed to an armchair by the fireside on the sixth day with manifest advantage.

Since I began to employ this method of procedure in 1899 I have done seven enterectomies for gangrenous herniæ. Of these five have recovered. One of the fatal cases died from obstruction due to an old fibrous band pressing on the bowel after its return; the other case did well for several days and then slowly developed peritonitis, starting from the remains of the infected sac which I had unfortunately not drained and which having contained the cæcum was difficult to shut off by suture from the abdominal cavity. There was no failure of any kind at the seat of the anastomosis.[8]

These results, I feel, justify the hope that primary enterectomy may often take the place of the formation of an artificial anus in gangrenous hernia if the principle of *excising a large tract* of damaged gut above the constriction is followed for the reasons given above.

ON THE RELATION EXISTING BETWEEN URIC ACID EXCRETION AND THE BREAKING DOWN OF THE WHITE CORPUSCLES.[1]

BY OLIVER K. WILLIAMSON, M.A., M.D., B.C. CANTAB., M.R.C.P. LOND.,

MEDICAL REGISTRAR TO THE MIDDLESEX HOSPITAL; PHYSICIAN TO OUT-PATIENTS AT THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.

THE important fact that uric acid can under certain conditions be experimentally produced from the white blood corpuscles was first observed by Horbaczewski.[2] Following his research the relation of uric acid excretion to leucocytosis has been worked at by many writers from the clinical standpoint; among these Kühnau[3] and Richter[4] in Germany, Douglas[5] in this country, and Zarnier,[6] Giajmis,[7] and Reale[8] in Italy may be mentioned. If it be true that uric acid is formed from the white corpuscles, the fact is to be explained by its production from the nuclein contained in these cells, either as a result of their destruction or in consequence of their metabolism. The conclusions arrived at by the above-mentioned observers have, when definite, been by no means in agreement. Kühnau, in an extensive and careful research, showed that, following the crisis of lobar pneumonia, at which period there is an increased destruction of the white cells, there is an increase in the daily amount of uric acid excreted. Making observations in various other diseases he found that following a decrease in the leucocyte count there is in most cases a corresponding increase in the daily amount of excretion of uric acid, an increase which he considers is caused by the increase in destruction of the white blood corpuscles. He further showed that in leucocythæmia, in which condition the number of white cells in the blood is largely increased, the daily excretion of uric acid is also markedly increased.

With regard to his observations showing a rise in the amount of excretion of uric acid following a fall in the leucocyte curve, I would point out that the latter may be referable not to an increased destruction of leucocytes but simply to a diminished production. As regards his researches in leucocythæmia, Milroy and Malcolm[9] have shown that in medullary as well as in lymphatic leukæmia, and Hale White and Hopkins[10] have demonstrated that in medullary leukæmia, the daily amount of excretion of phosphoric acid is diminished, so that the increased amount of uric acid excreted in these diseases can hardly be ascribed to an increase in the breaking down of the white corpuscles. The other observers mentioned (with the exception of Richter who lays stress on the importance of making observations extending over a considerable period of time) contented themselves with making in each case at most two or three observations on consecutive days of the numbers of white cells in the blood and comparing these with the amounts of uric acid excreted on the same days. Now inasmuch as the physiological amount of the daily excretion of uric acid varies for different individuals within wide limits (between 0·2 gramme and 1·5 grammes) it is obvious that the amount excreted in a particular individual under pathological conditions may be very largely increased without this amount exceeding these limits. It would seem to follow from this that observations of the ratio between the average amount of the daily excretion of uric acid and the average number of white corpuscles in the blood in a particular case are of less value than consecutive observations in the same case, showing alterations in the one side by side with alterations in the other. It must be confessed that, apart from Horbaczewski's experimental work, the only convincing observations as to uric acid being formed from the white blood corpuscles are those of Kühnau on pneumonia.

My object in making the observations which are recorded below has been to determine in pathological conditions the times in each case observed at which an increased destruction of white cells is taking place, and to notice whether this is followed by an increase in the amount of the daily excretion of uric acid. With this end in view daily observations were made of the number of white corpuscles in the blood for many consecutive days, whilst corresponding daily estimations of the total amount of uric acid excreted in the urine in the 24 hours were also performed. It is fairly obvious that in any condition such as advanced pulmonary tuberculosis, in which there is a leucocytosis for a considerable period of time, there must be associated with this (always assuming that the leucocytes concerned are not specially long lived forms) an increase in the amount of the daily destruction of the white cells. When I refer below to increased destruction (as evidenced by certain alterations in the differential count to be presently explained) it must be understood that I mean an increase in the amount of destruction of the white cells over and above what has just previously been taking place (i.e., a relative increase in the breaking down of the white blood corpuscles). In order to prove that a rise in the amount of uric acid excreted is due to an increase in the destruction of the white cells, it is necessary to show a corresponding rise in the amount of phosphoric acid excreted; accordingly, besides daily observations of the amount of uric acid excreted, estimations of the daily amount of excretion of phosphoric acid were also made. As Milroy and Malcolm say, "it is hardly likely that there is a marked retention of the phosphoric acid in the organism and if there be not, then the absence of the rise in the phosphorus excretion negatives the view that the alloxur bodies are derived from the direct breaking down of the nucleins."

---

[8] Since the above was written I have successfully operated on an eighth case of gangrenous hernia and excised the necrosed portion, consisting of a strangulated Meckel's diverticulum.

[10] Hale White and Hopkins: On the Excretion of Phosphorus and Nitrogen in Leukæmia, Journal of Physiology, 1899.

Now an increased destruction of the white cells means a diminution in the number of the old cells, the young cells either not diminishing at all, or at any rate not to a corresponding degree. Inasmuch as the polymorphonuclear neutrophiles—in this article I have adopted the classification of Cabot[11]—form by far the larger proportion of the white blood corpuscles in a healthy individual and are those concerned in ordinary leucocytosis, we will first consider them. Ehrlich's[12] view that the myelocyte and polymorphonuclear neutrophile represent different stages in the life history of one variety of cell, the myelocyte being the young cell, is generally accepted as correct. It is further probable that the small lymphocyte is quite distinct from these, being from first to last a small lymphocyte and nothing else, and that the large lymphocyte is, like the myelocyte, a young form of the polymorphonuclear neutrophile about the origin of which, however, we know less than in the case of the myelocyte. In examining a stained blood film from a case in which there is, or has recently been, a leucocytosis, forms intermediate in appearance between the myelocyte and the polymorphonuclear neutrophile are to be seen in varying numbers. The nucleus of one of these cells stains evenly and lightly; it is circular or oval or sometimes bilobed as if about to undergo division; moreover, at times not only the nucleus but the whole cell body is bilobed: the granules of the cell are similar to those of the polymorphonuclear neutrophile. Since all transition stages between the myelocyte and the polymorphonuclear neutrophile are represented by these cells it is clear that they are intermediate in age between these two varieties or are, in other words, simply young polymorphonuclear neutrophiles. Now if it be found as the result of observations made on two successive days that the polymorphonuclear neutrophiles are diminished in absolute number, the "young cells" (including the myelocytes) not being diminished or, at any rate, not being diminished to a corresponding degree, it may be assumed that a destruction of this form of white corpuscle has taken place. If, on the other hand, these show that whilst there has been a diminution in the absolute number of polymorphonuclear neutrophiles the number of the "young cells" is also markedly lessened, an increase in destruction of this variety of cell cannot be assumed, but rather a diminished production. In order to determine the absolute numbers of each variety of white corpuscle stained films were prepared and differential counts were made from specimens taken at the same time as those specimens from which the simple blood counts were made. By means of these differential counts one is thus able to obtain confirmatory evidence of the breaking down of the
whit
inasr
old f
cell
there
phosphoric acid.

From an examination of the results it will be seen that in 17 out of 20 instances in which an increased excretion of phosphoric acid follows a fall in the white blood corpuscle curve, pointing to an increased destruction of white corpuscles, there is associated with this increase a corresponding increase in the amount of uric acid excreted. In 13 instances there is confirmatory evidence of increased destruction of the white cells obtained from the differential counts, whilst in three instances this confirmation, owing to the absence of differential counts, could not be obtained. In five instances the examination of the differential counts gave a directly opposite interpretation to the study of the white corpuscle and phosphoric acid curves, the one pointing to increased destruction and the other not. Most of the observations were on cases of advanced pulmonary tuberculosis; in these we may fairly assume, as Haig[13] has pointed out, that there is no retention of uric acid within the body. If we carefully examine the curves we shall see that in those cases in which there are great and sudden variations in the number of white cells, there are also great and sudden variations in the amounts of uric acid and phosphoric acid excreted. This tends to confirm the theory that uric acid is derived from the white corpuscles (compare, for instance, Cases 1 and 5, on the one hand, with the earlier observations on Cases 10 and 11 on the other). It will also be observed that in the case of the three children (Cases 1, 2, and 3) there is, relatively to the body-weight, more uric acid and phosphoric acid excreted than in the case of the adults. This may be explained by assuming a more rapid destruction of the white cells in the former case than in the latter. This is confirmed by reference to the curves, when we find that the rise of uric acid and phosphoric acid follows more closely on the fall of the white corpuscle curve than in the case of the adults.

As regards methods, the white blood corpuscle counts were made by the Thoma Zeiss hæmacytometer, the diluting solution used being a ½ per cent. solution of acetic acid in water coloured by gentian violet; the differential counts were made from films fixed by heat and stained by a modification of Ehrlich's triacid stain. The uric acid was estimated by Hopkins's method (by Folin's modification in Case 9). 100 cubic centimetres of urine were used for each estimation and the total quantity passed in the 24 hours being measured the total quantity of uric acid passed in the 24 hours was thus calculated. The phosphoric acid was estimated by means of the volumetric method with uranium nitrate, 50 cubic centimetres of urine being used for each estimation and the total quantity passed in the 24 hours being calculated as in the case of the uric acid. I append tables (Tables I. to XI.) and curves of the results obtained in the different cases. The observations were made on 11 patients and the results include upwards of 100 estimations of uric acid. The numbers in the columns headed "uric acid" and "P_2O_5" (phosphoric acid) are the amounts (in grammes) of these substances respectively passed in the urine in the 24 hours. The columns headed "W.B.C." show the number of white blood corpuscles per cubic millimetre. The columns under the headings "young cells" give the percentage of cells having the characters intermediate between those of myelocytes and polymorphonuclear neutrophiles as described above. Owing to unavoidable accidents the continuity of the observations was unfortunately broken in places and in the short description of the results which I shall now give only those differential counts will be discussed which have a definite bearing on the subject of this paper.

CASE 1.—The patient was a boy, aged ten years. His weight was 3 stones 13 pounds. He had lymphadenoma with intermittent temperature. On examining the curves and tables it will be seen that there are two rises in the phosphoric acid curve corresponding with two rises in the uric acid curve following falls in the white corpuscle curve; also rises in the phosphoric acid and uric acid curves corresponding with a fall in the white corpuscle curve. From a study of the differential counts (Table I.) we find evidence of breaking down (increased destruction) of the white cells between March 15th and 16th, 22nd and 23rd,

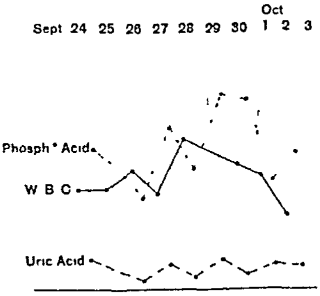
and finally April 16th and 17th, such evidence being, as I stated above, a decrease in the absolute number of polymorphonuclear neutrophiles, whilst the number of the myelocytes and young cells remains the same or even increases. These three occasions correspond with the three above-mentioned falls in the white corpuscle curve.

CASE 2.—The patient was a boy, aged seven years. He weighed 2 stones 10 pounds. He had chronic pulmonary tuberculosis and pyuria. There are seen to be marked rises of the phosphoric acid and uric acid curves (on Sept. 27th and 29th) respectively following falls in the white corpuscle curve. Following the last fall in the white corpuscle curve is a rise in the phosphoric acid curve but not in the uric acid curve. From the differential counts (Table II.) there is evidence of breaking down of the white corpuscles between Sept. 26th and 27th, also between Sept. 30th and Oct. 1st, or in two out of the three instances in which a study of the three curves points to increased destruction of the white cells. Between Sept. 28th and 29th no differential counts were made.

FIG. 2.



CASE 3.—The patient was a male, aged seven years. His weight was 3 stones. He was suffering from chronic pulmonary tuberculosis. Here we find two rises in the phosphoric acid and uric acid curves immediately following falls in the white corpuscle curve. From examination of the differential counts (Table III.) there is evidence of increased destruction between Oct. 11th and 12th corresponding to one of these two falls. Between Oct. 16th and 17th, corresponding to the other white corpuscle fall, there is no evidence of increased destruction from the differential counts, except, perhaps, in regard to the small lymphocytes.

CASE 5.—The patient was a male, aged 21 years, suffering from caseous pulmonary tuberculosis. He died on June 30th. On examining the table (Table V.) and curves we see two well-marked rises in the phosphoric acid and uric acid curves following falls in the white corpuscle curve, also a slight rise of each following a fall in the white corpuscle curve. In only one instance is confirmatory evidence of increased destruction to be obtained from the differential counts—viz., between May 16th and 17th. Between May 20th and 21st and 22nd and 23rd there is no confirmatory evidence of increased destruction.

CASE 6.—The patient was a female, aged 21 years, suffering from caseous and miliary pulmonary tuberculosis. Unfortunately, no estimations of phosphoric acid and no continuous differential counts were made in this case. It may be noted, however, that after each fall in the white corpuscle curve there is a rise in the uric acid curve, the most marked rise (that between Jan 13th and 15th) occurring after the longest and most marked fall in the blood corpuscle curve. The low white corpuscle counts in this case should be noted. (Table VI.)

FIG. 6.

CASE 7.—The patient was a female, aged 30 years, suffering from caseous and miliary pulmonary tuberculosis. Here we see that after the fall in the white blood count between

Oct. 28th and 29th there are marked rises in the curves of phosphoric acid and uric acid. No confirmatory evidence of increased destruction is obtainable from the differential counts between Oct. 28th and 29th. (Table VII.)

CASE 8.—The patient was a male, aged 21 years, suffering from caseous pulmonary tuberculosis. Here there is nothing in confirmation of the theory that uric acid is produced by the destruction of the white blood corpuscles. There are two rises in the phosphoric acid curve following falls in the blood corpuscle curve between Sept. 10th and 11th and Sept. 16th and 17th respectively, but neither of them corresponds with a rise in the uric acid curve. From the differential counts we find that there is evidence of increased destruction of the white cells between Sept. 10th and 11th, 12th and 13th, and finally 16th and 17th. (Table VIII.) The first and last of these three occasions correspond then to the two periods of increased destruction as shown by the white corpuscle and phosphoric acid curves; in the second case, however, there is no succeeding rise in the phosphoric acid curve and therefore no other evidence of increased destruction.

CASE 9.—The patient was a male, aged 40 years, suffering from chronic pulmonary tuberculosis. In this case it is probable that a rise in the phosphoric acid and uric acid curves occurred soon after the 31st inst., following a slight fall in the white corpuscle curve. There is evidence of increased destruction from the differential counts between August 29th and 30th. (Table IX.) Here there is little evidence either for or against the theory.

CASE 10.—The patient was a male, aged 62 years, suffering from chronic pulmonary tuberculosis, bronchitis, and emphysema. Here we see two rises in the phosphoric acid and uric acid curves, slight ones on Nov. 13th and very marked ones on Nov. 16th, following two falls in the white corpuscle curves. From a study of the differential counts we obtain confirmatory evidence of increased destruction of the white

corpuscles between Nov. 12th and 13th, corresponding to the first of these occasions Corresponding to the second there is no confirmatory evidence, seeing that no differential count was made either on Nov 14th or 15th (Table X.)

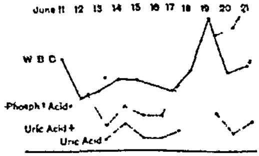
CASE 11 —The patient was a female, aged 42 years She was suffering probably from a new growth of the mediastinum. She died on June 22nd In this case there are three corresponding rises in the phosphoric acid and uric acid curves following respectively three falls in the white blood corpuscle curve There is, corresponding to these three occasions, confirmatory evidence of increased destruction of the white blood corpuscles between June 11th and 12th, 14th and 15th, and finally between the 19th and 20th. (Table XI)

FIG 11



The mark + represents a reading of phosphoric acid

To Dr. Eustace Smith and to my colleagues at the City of London Hospital for Diseases of the Chest, Victoria Park, Dr G A. Heron, Dr E C Beale, Dr. H. Sainsbury, Dr T Glover Lyon, and Sir Hugh Beevor, I am indebted for permission to use the results obtained from cases under their care

A FORM OF REMOVEABLE DEEP SUTURE.

BY F. R S MILTON, M R C S ENG, L R C P. LOND,
PROFESSOR OF CLINICAL SURGERY AT THE MEDICAL SCHOOL CAIRO, SURGEON TO, AND SURGEON IN CHARGE OF GYNÆCOLOGICAL WARDS AT, THE KASR EL-AINI HOSPITAL, CAIRO

ALTHOUGH an aseptic buried suture should remain buried and never be heard of further, still it does sometimes happen that such a suture will, after a time, make its presence known by causing the formation of a pustule to be followed by a sinus which will not heal until the offending stitch has been removed This may happen after the completely aseptic healing of the original wound and even after every precaution has been taken in the preparation of the suture material This reappearance of the suture is always a cause of annoyance to the patient and of heart searching to the surgeon and, if a continuous suture has been used, as for instance, in the peritoneal suture after abdominal section, may necessitate the performance of an operation involving the opening up of the whole original wound. In order to get over this difficulty it is necessary to devise some form of suturing in which the deep suture, although practically buried, may still be removed at any period after the healing of the wound Again, after many operations, such as those involving suturing at the bottom of cavities, such as in the vagina for vesico-vaginal fistulæ or in colporrhaphy, the patient has to undergo what may cause her almost more suffering than the original operation when the time comes for removing the stitches, and here again the use of an easily removeable suture would be of immense advantage both to the surgeon and to the patient.

It is evident that to be capable of removal at a period subsequent to complete inclosure in a healed wound, any suture of more than a single point must be a continuous one and the form of continuous suture most easily removed by a single application of force would seem to be that which is commonly known as the ordinary machine chain stitch and in order to make use of this it is only necessary to employ a form of needle which will take the entering and returning thread through the same hole This, then, was the first form of stitch which I experimented with. In working this out on inanimate objects it answered perfectly well, but when it came to applying it to the living subject it was found that during the process of healing in the wound the chain got, as it were, fouled by the uniting tissue and the stitch would not pull out easily. Being dissatisfied with this I then tried the other form of sewing-machine or "lock" stitch, and this was found quite satisfactory and perfectly easy of removal provided certain points in its application were attended to.

In the ordinary sewing-machine the efficiency and neatness of the stitching depend upon preserving the ratio between the tensions of the two threads employed. If the tension is properly regulated the interlocking of the threads will take place in the substance of the material under suture, whereas if the tension of one of the threads be greater than that of the other the interlocking of the threads will take place on the surface of the material and on the side of the thread with the highest tension. By using two threads with different pliability in surgical suturing the same effect can be produced as would be caused by extreme difference in the tension in machining; thus, if one thread be of silk and the other of, say, stiff steel wire it is obvious that instead of the threads interlocking in the substance of the material they will hardly interlock at all, but the more pliable silk will simply pass round the stiff wire and the turns will all be on the side of the material to which the wire is applied, and, further, it will be found that on pulling the wire this can be easily withdrawn and in consequence the silk, having lost its support, can also be withdrawn with the slightest pull.

The method of introducing the suture is of the simplest. All that is required is a mounted needle with an eye near the point; through this is threaded a long piece of silk. This forms the primary thread; the secondary thread is best formed by a stout piece of silkworm-gut which is sufficiently rigid to avoid kinking and being drawn into the sutured tissue. Supposing the peritoneum is to be sutured after a laparotomy the procedure will be as follows:—The two layers of the peritoneum which are to be sewn together are defined; the mounted needle, threaded, with the long end of the thread on the left hand or upper side of the needle when held as it will be when piercing the tissue, is passed from the operator through both layers of the peritoneum, beginning at the lower angle of the wound. The needle is then withdrawn, leaving a loop of silk protruding through the layers of peritoneum on the side of the assistant; through this loop the assistant passes the end of the silkworm-gut, from below upwards, and the loop is withdrawn flush with the assistant's side of the united flaps. The needle, not having been unthreaded, is again thrust through the flaps for the second stitch and again withdrawn, leaving a loop as in the first instance; the silkworm-gut is threaded through this second loop and the process is repeated till the whole of the flaps are united; these being held together by a series of silk loops, the primary thread, held in position by the secondary thread of silkworm-gut passing through the loops on the assistant's side. The needle is next unthreaded, leaving a fairly long end to the silk. There will be now on the face of the wound, on the side of the surgeon, the two ends of silk, one entering the peritoneal flaps at the lower end of the wound and the other leaving the peritoneum at the upper end, and on the side of the assistant the silkworm-gut thread passing through the silk loops and also with long ends, one at the lower end of the wound and the other at the upper end. The silkworm-gut thread should now be put on the stretch and pulled gently backwards and forwards to see that it is nowhere kinked and that it can be withdrawn. This having been done, the four ends, two silk and two silkworm-gut, are each in turn threaded on an ordinary needle and made to pierce the skin on its own side of the wound and are left thus whilst the wound in the abdominal wall is sutured in the ordinary way. This having been done the two lower ends of the peritoneal suture, being one of silk and the other of silkworm-gut, are then tied together and cut to a convenient length. The same is done with the two ends at the upper end of the wound and the process is complete.

When it is required to remove the deep stitch, which may be any time after the wound is healed, all that is required is to cut the lower united stitches on the silk side of the knot *and the upper stitch on the gut side of the knot, or vice versâ*, and to pull out first the silkworm-gut stitch which will offer no resistance, and then the silk stitch which having lost its support can be pulled out with equal facility.

The suturing itself can be done quite as rapidly as the ordinary continued suture and the only point requiring special attention is not to pull the silk loops so tight that they drag the silkworm-gut thread into the stitch hole or on to the silk side of the wound.

The method is applicable to any form of buried suture which it may be desirable to remove after healing, except that if the suturing has to take a curve of more than about a sextant two or more separate silkworm gut threads will have to be used in following the curve; otherwise, if the one thread has to curve round too great a part of a circle it will be found to drag on the loops on an attempt at withdrawal and will not run.

There would appear to be no limit, in reason, to the time that the suture may be left in position without causing trouble, provided the part be kept aseptic; thus, in cases of radical cure of hernia I have kept the stitches closing the ring in position for 15 days without any sign of suppuration or irritation and with no indication that such was likely to occur, and at the end of that time have removed the stitches without the slightest difficulty.

Up to the present I have employed the stitch in cases of laparotomy, in radical cure of hernia, in suprapubic cystotomy, for suturing the pleura in cases of abscess of the liver, and in colporrhaphy, and have found it to answer very well.

Cairo.

A CASE OF TYPHOID PANCREATITIS.

BY B. G. A. MOYNIHAN, M.S. LOND., F.R.C.S. ENG.,
SENIOR ASSISTANT SURGEON TO THE LEEDS GENERAL INFIRMARY; CONSULTING SURGEON TO THE SKIPTON HOSPITAL AND TO THE MIRFIELD MEMORIAL HOSPITAL.

IT has been generally recognised, since Riedel in 1892 first drew attention to the fact, that chronic pancreatitis is not infrequently dependent upon the irritation of gall-stone disease. The constantly recurring attacks of cholangitis aroused by the passing of a stone down the cystic and common ducts, the impaction of a stone in the lower end of the common duct, and especially its lodgment in the ampulla of Vater, may all be the determining causes of a chronic inflammation of the pancreas.

Among causes other than gall-stones which are capable of originating an acute inflammation of any part of the bile passages typhoid fever, as shown by Murchison, Keen, and many others, takes a prominent place. The bacillus typhosus may be found in the bile for many months or even years after an attack of typhoid fever. In one case a pure culture of the organism was obtained from the bile in the gall-bladder after seven years. Since the common bile-duct and the duct of the pancreas have a common opening into the duodenum at the ampulla of Vater it is not difficult to understand how an ascending infection attacking the bile passages may also affect the canal of Wirsung. In the following case there was a condition of typhoid pancreatitis associated with an infection of the gall-bladder by the bacillus typhosus.

The patient, a boy, aged 13 years, who was sent to me by Dr. W. A. H. Waite of Leeds, was admitted to the Leeds General Infirmary on March 2nd, 1903. The history of the case was that he had been in his usual good health up to September, 1901. In that month he had typhoid fever, from which he made a slow but satisfactory recovery. At frequent intervals since his convalescence he complained of attacks of pain in the upper part of the abdomen. When asked to point out the seat of the most severe pain he laid his hand across the epigastrium. The pain on several occasions had lasted for three or four hours and had been accompanied by feelings of nausea and, though rarely, by vomiting. In November, 1902, for the first time such an attack was followed by jaundice which lasted for several days and then gradually cleared away. Almost every week since November similar attacks of pain, varying in intensity, had occurred and the jaundice had deepened slightly after each attack. The jaundice had never cleared away completely, though it had varied much in depth of tinge. There had never been *any elevation of temperature when the pain* had come and there had been neither shivering nor flushing. For the last three months the appetite had been poor and the boy had become considerably emaciated.

On examination of the abdomen there was distinct tenderness in all the region above the level of the umbilicus Nothing abnormal could be felt A diagnosis of typhoid infection of the gall bladder, probably resulting in gall stones one of which had stayed in the common duct, was made On March 6th the abdomen was opened The gall bladder contained bile but no stones There were no adhesions around the bladder or the bile ducts There was no stone in any part of the bile passages The cause of the jaundice was found in the pancreas The head and much of the body of the pancreas were found to be at least twice as large as the normal and almost as hard as stone I have never felt even in old standing cases of chronic indurating pancreatitis a gland so intensely hard as this was The common duct was obviously buried in a mass of densely hard inflammatory material in the head of the pancreas The gall-bladder was aspirated and about half an ounce of bile was withdrawn into a sterilised vessel A drainage tube was sutured into the gall bladder and the abdominal wound was closed in the usual way The bile was handed over to Dr J A. Cairns Forsyth for examination His report read as follows —

> An agar tube was inoculated with the bile The resulting growth was examined and found to be composed of bacilli resembling the bacillus coli or the bacillus typhosus The bacilli had the following properties (1) *in fluid gelatin they cause a uniform turbidity without* the formation of any flocculi (2) they do not coagulate or curdle milk and (3) they do not produce an acid reaction on litmus agar The organisms are therefore typhoid bacilli

Dr Forsyth then examined the blood for Widal's reaction and reported as follows —

> The serum gave a positive reaction—1 in 20 instantaneously, 1 in 60 in ten minutes and 1 in 100 in 40 minutes.

The gall bladder was drained for four weeks Recovery was uninterrupted and in all respects most satisfactory

This case is, so far as I can ascertain, the first in which an inflammation of the pancreas due to typhoid fever has been recognised I have operated now upon 13 cases of chronic pancreatitis, but in no instance have I observed so gross an alteration in the size and consistence of the gland At the end of three weeks the bile discharged from the gall bladder was examined by Dr Forsyth and was found to contain very large numbers of typhoid bacilli I then ordered urotropine in ten grain doses thrice daily, the dose being increased to 15 grains four days later On the eleventh day after the commencement of the giving of the drug the bile was again examined and was found to contain no typhoid organisms, only "a few cocci "

Leeds

SOME OBSERVATIONS ON MOVEABLE KIDNEY[1]

BY T E GORDON, M B DUB, F R C S IREL,

SURGEON TO THE ADELAIDE HOSPITAL DUBLIN

I WISH in this communication to draw attention to some points of interest relative to moveable kidney and to show the conclusions to which I have come I have seen very many cases of this condition and I have notes of 12 cases in which I performed a fixation operation Of these 12 cases all the patients were women except one who was a young man In all of these cases I operated by the same method—i e, that recommended by Morris—with one modification In all the result was aseptic I do not think permanent complete fixation has been the rule but, as Edebohls has pointed out, a certain degree of return of mobility is not inconsistent with perfect success as regards the relief of symptoms

It is now well recognised that moveable kidney is a cause of various and diverse symptoms—that it may induce vomiting and other gastric manifestations jaundice and hepatic colic or symptoms which belong to the kidney itself, and that it may be associated with a neurasthenic condition With such diversity of symptoms it can readily be understood that moveable kidney is a common cause of mistaken diagnosis Sometimes cases of moveable kidney are mistaken for something else—e g, those in which vomiting occurs are supposed to be cases of gastric ulcer or those with jaundice to be cases of gall stones On the other hand, symptoms due to something else may be supposed to be due to moveable kidney and this kind of mistake is apt to be attended with serious consequences, as in a case to which I must refer in some detail presently There are two facts which when fully realised ought to safeguard one against both classes of error to some extent First it should be remembered that moveable kidney is of exceedingly common occurrence and often is the sole cause of some of those symptoms to which I have alluded. In the second place, it should still more carefully be borne in mind that the moveable kidney, whatever degree of mobility it may possess, may be a cause of no symptoms

We may conveniently arrange these cases of moveable kidney which cause symptoms into certain groups as follows (1) those with slight discomfort, such as a dragging sensation and associated with vague general ill health, with or without hysterical manifestations, (2) those in which the symptoms are of the gastro intestinal type, (3) those with hepatic symptoms, and (4) those having distinctly renal symptoms I think that the last must be very uncommon At all events, I have not met with a single case and I will not therefore allude to them further

Those cases of the first group with hysterical symptoms present special difficulties Hysterical women often have a moveable kidney, they are often unaware of this and have no symptoms referable to it In these circumstances it is obviously a folly to advise nephropexy or, indeed to make the patient aware that her kidney is moveable. If, however, she is made aware one way or another that she has a moveable kidney an operation *may* do good I have had one remarkable success in the case of a woman of this class

CASE 1 —The patient was emaciated, complained of pain and fulness after eating, was much constipated, and was quite unfit for work She was Dr H. T. Bewley's patient and having fruitlessly tried ordinary remedies he handed her over to my care I fixed her kidney in January, 1901, kept her in bed for six weeks, and had her massaged during part of this time and well fed I saw her again about six months after the operation and found her in perfect health scarcely to be recognised as her face had so filled out and able to perform her day's work without discomfort She had put on three stones in weight I can justly claim this as a success, but in so doing I must confess to a failure in another case of the same class

I have now something to say about the more interesting and satisfactory group presenting gastric or gastro intestinal symptoms I may begin by recording a fortunate case as I must end by telling of one which was most unfortunate

CASE 2 —The patient was a young woman who had been treated for several years for a supposed gastric ulcer She had suffered from repeated attacks of vomiting and pain. The pain was at first felt in her back in the lumbar region but for the last two or three years in the right hypochondrium An attack might last with remissions from a few days to a month and then she might have an interval of perfect health for several months It is specially noted by Dr G Peacocke, under whose care she was in the hospital, that the pains and vomiting were quite independent of food, and, further, it was stated that an attack never commenced while she was in bed and that it was sometimes relieved by lying down She had on no occasion vomited blood Dr Peacocke found her right kidney very moveable and at his request I performed a fixation operation This was in October, 1901 and since then the patient has been in perfect comfort and has only vomited once

This case is an *instance of the very common mistake of* assigning to organic disease of the stomach symptoms that are due to moveable kidney The differential diagnosis is, I think, sufficiently brought out in the details which I have given As an example of the opposite kind of mistake I may just mention a case I saw a year or two ago in which with [illegible]

CASE 3 —The case was Dr F T Heuston's and an exploratory laparotomy showed the tumour, which I thought was a moveable kidney, to be a massive cancer of the stomach which had been dragged by its weight into an unusual position. As comment, I may point out that the kidney like tumour was on the left side that the right kidney was not moveable, and that a left kidney is rarely if ever moveable without its fellow on the right side being moveable also

Moveable right kidney may be a cause not only of pain and vomiting but also of an actual dilatation of the stomach and it has been fully established that this dilatation may be due to peritoneal bands formed by the dragging of the kidney.

---

[1] A paper read before the Dublin Biological Club on March 25th, 1903

CASE 4.—About a year ago I operated upon a young woman, one of Dr. Peacocke's patients who was suffering from pain and vomiting and presented the physical signs of a moderately dilated stomach. I fixed her right kidney which was very moveable and for six months her symptoms seemed to have been relieved. At the end of this time, however, she began again to suffer and quite recently she was again admitted to the hospital. At an exploratory laparotomy I found the stomach below its normal position, it was large and toneless, but with no evidence of kinking or other cause of obstruction at the pylorus. The pancreas and second stage of the duodenum could be lifted right away from the back of the abdomen. No fixing of the kidney (the kidney in this case had remained quite well in place since the operation a year previously) nor, indeed, any other operation could be expected to do good under these conditions. Without attaching too much importance to this case, which may be quite exceptional, I may at least suggest caution in assigning to moveable kidney a dilatation of the stomach even though the mobility be marked, the patient young, and previous gastric ulceration improbable.

Let me now relate the history of the unfortunate case to which I have referred.

CASE 5.—A woman, aged 37 years, was admitted to hospital on Nov. 16th, 1901. Four years, and again one year, previously she had suffered from pain and flatulence after food. She did not vomit and was not constipated. In February, 1901, she had what was believed to be an attack of influenza. At this time purgatives caused pain about the umbilicus. In May she had an attack of acute pain in the right side and pain after passing urine and this lasted three days. At the same time she had again pain after food. She also vomited and passed some blood per rectum. In June she lifted a heavy weight and a return of pain and vomiting followed. In July and in September she had other attacks of pain and she vomited black material. When admitted to hospital in November she was very thin and she said that she had lost much flesh. Her abdomen was quite flaccid and not distended. No tumour could be felt anywhere, but fæcal masses marked out the course of the colon and she had a very moveable right kidney. The feculent masses were removed by a succession of enemata. On Nov. 30th I sutured the moveable kidney in place and all went well subsequently for a time. In the middle of December, however, symptoms of obstruction appeared and gradually increased. Great peristaltic waves were observed and she got severe paroxysms of pain. I opened the abdomen on Dec. 15th and found a stricture of the sigmoid flexure. I incised the strictured part and I regret to say that the patient died on the 20th. The stricture was non-malignant. I have given an account of this case at some length because it has impressed upon myself a very important lesson regarding over-confidence in the diagnosis of moveable kidney as a cause of obscure abdominal symptoms.

It remains to say something of moveable kidney with hepatic symptoms, but I cannot do more now than briefly state my experience.

CASE 6.—I operated upon a female patient of Dr. Wallace Beatty in March, 1901, who had suffered from severe hepatic colic and was jaundiced at the time of operation. Her right kidney was very moveable and her gall-bladder was dilated. There was no gall-stone found though one was carefully searched for. I fixed the kidney and stitched the opened gall-bladder to the parietes. This patient has been quite well since.

CASE 7.—About a year ago Dr. Bewley saw with me a woman who was suffering from severe pain like that which a gall-stone causes. There was much tenderness in the right hypochondrium and when this became less we could quite easily make out a dilated gall-bladder and a moveable kidney. She was not at any time jaundiced. When the gall-bladder tumour disappeared she got an abdominal belt and has been in comfort since.

In addition to these cases I have seen two in which gall-stones and moveable right kidney were present together and still other cases in which with the moveable kidney jaundice was the only hepatic symptom.

With this personal experience it could not be but that I should be a believer in what is indeed commonly accepted as fact—i.e., that moveable kidney may induce symptoms scarcely to be distinguished from those due to gall-stones. Jaundice is common; the co-existence of gall-stones and moveable kidney is not uncommon; and there are now on record many cases of biliary colic similar to the case I have referred to (Case 6).

Now let me briefly state some of my conclusions. 1. That in neurasthenic cases nephropexy *may* do good seems to me proved by the first case I have described. 2. Vomiting and other gastric symptoms can certainly be cured, but if dilatation of the stomach is present a guarded prognosis must be given. I have narrated a case of failure in these circumstances but I have had in an analogous case a decided success. 3. The unfortunate case of mistaken diagnosis which I have described should make one most cautious in concluding that a moveable kidney is a cause of obscure abdominal symptoms. 4. Moveable kidney occasionally causes symptoms which exactly simulate those due to gall-stones, but seeing that the coincidence of moveable kidney and gall-stones is not uncommon it would be unwise merely to fix the kidney without a preliminary examination of the gall-bladder and ducts. Finally, whilst readily granting that most cases of moveable kidney cause no symptoms and therefore require no operation, there remain many which do cause symptoms and in a fair proportion of these an excellent result from nephropexy may confidently be anticipated.

Dublin.

APPENDICITIS WITH PROFUSE INTESTINAL HÆMORRHAGE CLOSELY RESEMBLING TYPHOID FEVER.

BY CHARLES R. BOX, M.D. LOND.,
ASSISTANT PHYSICIAN TO ST. THOMAS'S HOSPITAL AND TO THE LONDON FEVER HOSPITAL;

AND

CUTHBERT S. WALLACE, M.B., B.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO ST. THOMAS'S HOSPITAL AND TO THE EAST LONDON HOSPITAL FOR CHILDREN.

THE recognised complications of appendicitis are many but the occurrence of free hæmorrhage from the bowel is of great rarity. Several authors have drawn attention to the difficulties which in some cases attend the differentiation of appendicitis and typhoid fever but none of these appear to mention the possible occurrence of free bleeding from the bowel in the former disease.

A man, aged 51 years, whose health had for some weeks been indifferent but who had never before complained of similar abdominal symptoms, was one day seized with pain in his abdomen. The pain was referred to the right iliac region and was accompanied by vomiting. The temperature was 102° F. and physical examination revealed some tenderness in the region of the liver and gall-bladder. The pulse was poor; it varied from 110 to 150, being accelerated by the slightest exertion. The conjunctivæ were yellowish and there was a considerable trace of albumin in the urine. Intermittent albuminuria had been present for some years. The patient had lived freely and in consequence of his symptoms was restricted to a milk diet and kept in bed. The pain and vomiting were very transient and at the end of a week his condition appeared to have greatly improved. A few days later he was allowed to get up and went into his grounds. This resulted in an alarming attack of faintness and led to his being seen on the sixteenth day of his illness in consultation with Mr. W. Cox of Winchombe, to whom we are indebted for many details. The patient's mental condition was quite clear. The temperature was 102·2° and the pulse was 120, intermitting occasionally. The respirations were 40. The tongue was clean and moist. No actual pain was present but rather a feeling of fulness in the abdomen. For several days there had been diarrhœa, but this was attributed to the use of Kutnow's powder. Just before he was seen there had been a smart hæmorrhage from the bowel, more than half a pint of bright blood being passed. This was shortly followed by a loose, peasoup-like, and very offensive motion.

On examination the abdomen was found to be rather prominent and more resistant on the right side than on the left. There was a moderate generalised œdema of the tissues of the trunk and legs, but the œdema was certainly more marked in the iliac region and loin of the right side and here the skin was a little reddened, possibly from the attitude in which the patient lay. On percussion fixed dulness was obtained in the right loin and this extended well up to the base of the right lung, both in the axillary line and posteriorly. The breath sounds were rather faint at the base of the lung. The edge of the liver was felt below the ribs; it was not much enlarged, was not hard, nor was it tender. Tenderness was, however, complained of on deep pressure in the loin over the dull area. The spleen was not palpable and no typhoid spots were recognised. At night the patient was slightly delirious. 48 hours later the abdomen was more distended and tympanitic all over. Hæmorrhage from the bowel had twice recurred to the extent of half a pint of bright blood each time followed by some darker material. The abdomen was not tender and no fluid thrill of fluctuation could be obtained. The spleen could not be felt, but in the circumstances examination for it was not easy. There were still no rose spots. The nocturnal delirium continued and was more marked. The temperature was now 101·6° and the tongue was becoming dry.

Owing to the patient's condition a general anæsthetic was out of the question, so after due consideration it was determined to explore the right loin under infiltration anæsthesia. This was accordingly rapidly effected and the incision was carried down to the surface of the right kidney without evacuating any pus. Next morning a little more dark blood and some fæcal matter were passed by the bowel. The temperature had fallen to 98·4° but the pulse was 120 and intermittent and the quiet delirium was still present at night. The patient had been taking nourishment well throughout. On this day the result of the agglutinative reaction for typhoid fever was forthcoming and proved entirely negative. The nocturnal temperatures remained between 101° and 102°. Subsultus tendinum appeared. The abdomen remained distended but the patient suffered no pain. This was not due to narcotism, as during the illness only two small doses of Dover's powder and one injection of a quarter of a grain of sulphate of morphia were given. Strychnine and stimulants were used freely. Death occurred on the twenty-first day of illness.

Necropsy.—On opening the abdomen the most prominent object was the greatly distended and prolapsed V-shaped transverse colon with the omentum rolled up over it. Deep in the right iliac fossa was a discoloured and ragged abscess cavity, roofed in by œdematous omentum and containing a little pus. The appendix could not be recognised at all; it was either imbedded in the wall of the abscess or had sloughed right off. Along the outer side of the ascending colon was a series of comparatively recent adhesions with discolouration of the peritoneum. This track led up to a small deposit of fœtid pus which lay in the right kidney pouch between the kidney and the liver. The peritoneal area between the mesocolon and the mesentery was the site of a recent plastic peritonitis and the pelvic cavity contained a little pus. The hepatic flexure of the colon was discoloured and softened. It was adherent to both liver and gall-bladder and as soon as it was touched gas bubbled out. There was no trace of typhoid ulceration in either the large or the small bowel. The kidneys and liver were enlarged and probably fatty. The spleen was not much enlarged; it was soft and friable.

There are several points of considerable interest in this case, but our main object in recording it is to draw attention to the possibility of the occurrence of free hæmorrhage from the bowel in connexion with inflammation of the vermiform appendix. This rare complication, when it occurs, adds considerably to the difficulty in making a positive diagnosis. In our case although the signs seemed to point to appendicitis, yet the free hæmorrhage which occurred on the sixteenth and succeeding days of illness, together with the fever, nocturnal delirium, and extremely prostrate condition of the patient, caused grave suspicion that after all we might have to deal with a case of typhoid fever in which some peritoneal catastrophe had occurred. It is true that the temperature was not very high—102·2°—but severe intestinal hæmorrhage had occurred and was twice repeated. Of the temperature on the few days preceding the first hæmorrhage there is no record.

The unequivocal result of the agglutinative reaction for typhoid fever in this instance is an exceedingly good indication of its clinical value when properly performed, but such corroboration is hardly now needed. It is unfortunate that the exigencies of the situation prevented its earlier adoption. A curious feature throughout the course of the disease was the almost entire absence of pain after the first few days. Even firm pressure caused but little discomfort. This added to the difficulties of diagnosis, but in our experience it is not by any means unique in appendicitis. There was no opportunity of making a leucocyte count and even if made it is improbable that it would have yielded much information, since peritoneal infection even if [illegible] fever would have proved a distu[illegible] vessel from which the hæmorr[illegible] recognised at the necropsy, there can be no reasonable doubt that it was one of the branches of the superior mesenteric artery distributed to the hepatic flexure of the colon and that it was eroded by the collection of pus making its way into the bowel at this point.

The direction in which the suppuration extended within the peritoneum is the usual route taken when infection spreads upwards in the right lumbar region. In the recumbent position the pelvic brim is, so to speak, the watershed between the pelvic cavity and the loin, and an inclined plane leads along the ascending colon from this elevation to the right kidney pouch. The latter may not inaptly be compared to the gravy well of a dish and has the following boundaries: (erect position) *above*, the right half of the coronary and the right lateral ligaments of the liver; *internally*, the hilus of the kidney, the second part of the duodenum, the right aspect of the lesser omentum, and the foramen of Winslow; *externally*, the diaphragm and outside that the pleural sac and abdominal wall; *below*, the hepatic flexure of the colon and its attachment to the abdominal wall; and *anteriorly*, the renal impression of the right lobe of the liver. *The floor* of the pouch (in recumbency) is formed by the peritoneal aspect of the right kidney.

The peasoup-like and offensive motion which was passed soon after the first hæmorrhage and before the exploratory operation probably consisted of pus from the right kidney pouch and so accounted for the marked alteration in physical signs observed and also for the failure to evacuate pus when exploration was made in this locality.

SOIL NITRIFICATION *v.* THE INCIDENCE OF MALARIA AND OTHER MOSQUITO-BORNE DISEASES.

By ARTHUR R. WADDELL, M.D. GLASG.

DURING the course of some experiments which I carried out upon the destruction of mosquito larvæ I was impressed by the deadly poisonous effect which attenuated solutions of ammonia had on them. Using the strong liquor ammoniæ (specific gravity 0 880) as a standard, a solution of 1 in 4000 proved absolutely fatal to mature larvæ. Solutions so much weaker sufficed to kill younger larvæ that I computed that the presence in water of such minute quantities as only 1 in 20,000 or 30,000 would be prohibitive to the life of those newly hatched. Unfortunately, I was unable, owing to the shortness of our mosquito season in this country last year, to verify fully this estimate. My experiments, however, went to indicate that ammonia is poisonous to mosquito larvæ in all its combinations, the nitrogen unit being the index of effectiveness. Following this up, I came to the conclusion that here we have a force of enormous potentiality in the crusade against malaria and one, moreover, which is capable of practical application. This force consists in the effective nitrification of the surface waters and vegetation through the medium of the soil, the former checking the existence of the larvæ and the latter being [illegible] brought about in two ways, [illegible] f nitrogenous manures, and, secondly, by fostering the growth of certain plants belonging to the leguminosæ which are known by their peculiar root action to add to the nitrogen in the soil. As this peculiar property pertaining to this order of plants belongs more to the domain [illegible] be well if I [illegible] earth bacte[illegible] nitrogen from the atmosphere. They are accordingly referred to as nitrogen-fixing plants. The growth of these plants may be encouraged and stimulated by the use of phosphatic manures and also by inoculating the ground and the seed to be sown on it with cultures of these earth bacteria referred to, which are sold commercially under the name of "nitragin." The bacterial organisms themselves are, however, the real nitrogen bringers or nitrifiers, the leguminosæ being dependent upon their presence at the roots for healthy growth. These organisms abound in all good cultivated soils in which there is a sufficiency of phosphates, potash, and lime, the last especially being of vital necessity to them, and they are most active at a temperature of about 99° F., cold and absence of moisture inhibiting them. Good cultivation assists them. It is possible with their aid to grow crops extremely rich in nitrogen on a soil which is otherwise almost devoid of nitrogenous elements. Their presence in a soil is indicated by the growth upon the leguminosæ roots of small nodules sometimes as large as a small pea.

Evidence of the inhibitory influence of ammonia upon certain other low forms of animal life is found in some facts bearing on the nematode worms which live parasitically in the alimentary tracts of horses, cattle, and sheep, and set up in the last two a fatal wasting disease characterised by scouring diarrhœa. This disease, known as parasitic enteritis, is found to be persistently associated with certain pastures (called "teart" lands in the West of England) upon heavy moisture-retaining soils, the larvæ, in fact, living in the damp earth of these pastures, in mud, &c., and being thence transferred to the stomachs of their definitive hosts.

Experimenting on the adult thread-worms (strongylus) from a horse, practically identical for purposes of experiment with those of cattle, I got the following results by immersing them in solutions of ammonia (specific gravity 0·880): a strength of 1 in 2400 killed in three minutes; one of 1 in 4800 killed in five minutes; one of 1 in 9600 killed in 14 minutes; and one of 1 in 15,000 killed in 22 minutes. In a solution of 1 in 30,000 they were all dead at the end of five hours, the controls being alive and very active at the end of 24 hours.

That the nitrogenous elements in the soil play an important rôle in limiting the incidence of this disease is evidenced by a report[1] upon certain investigations concerning the grass grown on two contiguous patches of land, one not associated with the occurrence of parasitic enteritis in cattle fed upon it and the other notorious in this connexion and described as one of the "teart" lands referred to. Samples of hay grown on the respective areas were analysed with the following result:—

Table showing the Results of Analysis of Grass dried at 212° F.

—	From sound land not causing parasitic enteritis.	From "teart" land causing parasitic enteritis.
	Per cent.	Per cent.
Total nitrogen...	3·57	1·877
Albuminoid nitrogen	2·41	1·20
Nitrogen as nitric acid... ...	0·0107	0·010
Total acidity	0·088	0·104
Non-volatile acidity	0·039	0·100

In the same journal, in a report[2] upon the Improvement of Permanent Pastures by the application of phosphatic manures and the consequent growth of nitrogenising plants, it is stated that "the quality of the herbage generally has been so far improved that whereas cattle stocked here were formerly liable to be severely scoured through eating the grass and herbage this ailment has steadily declined until at present he has not a single case of it." So much for indirect corroboration.

From our very doors, as it were, comes more direct support. I allude to the great decrease of malaria in England during recent years. It has been suggested that the improved drainage of the land has been largely responsible for this, but other factors have helped and amongst these the increased nitrogenisation of the soil by the widened use of phosphatic manures, the extended growth of clovers, and the enormously increased use of nitrogenous manures have played an important part.

Thus far I have only had under consideration the direct effect of nitrogen upon mosquito larvæ, but the increased nitrogen in the tissues of plants grown upon fully nitrogenised soils should also prove inimical to adult mosquitoes feeding upon their juices. In this connexion we have already seen that crops exceedingly rich in nitrogen can be produced by the aid of the earth bacteria.

Malaria is such a world-wide scourge and the problem of its mitigation is so urgent that no time should be lost in making practical tests to establish the most effective way of employing soil nitrification against its distribution. There is plenty of scope for doing so. The irrigation areas in India are a case in point. In these malaria, from causes which need not be here discussed, has increased with the irrigation. Parts of the Roman Campagna, too, lend themselves readily for the purpose. An area of the cultivable portion should be taken in hand, one part nitrogenised directly and another part dressed with phosphatic manures and heavily planted with leguminosæ. I have no doubt that the area which has the good fortune to be so treated will immediately benefit and experience a marked amelioration of its malarial conditions. A word at this juncture upon an economic aspect of the question. Soil nitrification has this advantage over the generality of hygienic applications, it is *per se* directly profitable, the increased yield of produce more than compensating for a proper expenditure in effecting it.

Before concluding I would like to say that I am well aware that not all bodies of water, great or small, in which mosquitoes are likely to breed can be directly affected from the soil. I know, for instance, that subterranean oozings, rain-water accumulations, &c., not carrying nitrogenous elements in any quantity, if at all, will continue to afford the insects the facilities which they require, that the flooding and consequent waste of nitrogen incident to tropical rain storms will continue to be counteracting influences to nitrogenisation, but the main principle will remain, and this is what concerns me, that effective soil nitrification, scientifically pursued, will all the time act against the existence of the mosquito.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

SECONDARY HÆMORRHAGE FROM THE RIGHT EXTERNAL ILIAC ARTERY FOLLOWING PERITYPHLITIC ABSCESS.

By J. RAMSAY, M.S., M.B.MELB.,
SURGEON-SUPERINTENDENT, LAUNCESTON HOSPITAL, TASMANIA.

AS severe secondary hæmorrhage from the external iliac artery is not common in perityphlitic abscess I have thought fit to report the following case.

A boy, aged 10 years, was admitted into the Launceston Hospital, Tasmania, on August 29th, 1902, with a swelling in the right iliac fossa extending upwards to an inch below the level of the umbilicus. A fortnight before this severe pains in this region and down the right thigh had come on with anorexia, constipation, vomiting, feverishness, and sweating. The right thigh was kept flexed. On Sept. 15th, under chloroform, an incision was made obliquely over the swelling, splitting the muscle layers, and from three to four ounces of pus were evacuated, as well as a sloughy soft tubular mass about an inch long, which may have been a piece of slightly dilated appendix. The cavity was extraperitoneal and extended from the brim of the pelvis up behind the colon for a short distance. Gauze and a rubber tube were inserted for drainage. The temperature remained about normal after the operation and the rubber tube was finally removed on the eighth day, a little gauze being placed in the cavity. On the ninth day after operation he was seen to be very pale and a large quantity of blood had saturated the dressings and bedding. By packing the wound tightly with gauze the hæmorrhage, evidently arterial, was controlled, the pulse being weak and rapid. Normal saline enemata were given. On the eleventh day after operation the wound was re-packed gently; no fresh bleeding was taking place. That evening he had another severe arterial hæmorrhage from the wound which could be controlled by firm pressure over it. An anæsthetic was given; the wound was enlarged and the peritoneum was peeled up, but the hæmorrhage was so free that search for the bleeding point was impossible. It was controlled by pressure over gauze packing, whilst through a vertical incision, splitting the right rectus with the patient in the Trendelenburg position, the external iliac artery was ligatured transperitoneally just below its origin. There was no sign of a vermiform appendix on hasty examination. The vertical wound was closed with sutures and the old wound was explored. The severe hæmorrhage had ceased, but there was a little pumping from the distal part of a ragged sloughing portion of the external iliac artery which opened up the lumen of the vessel for about one and a quarter inches. A silk ligature around this distal part controlled the bleeding. The cavity was wiped with pure carbolic acid and packed with gauze. The pulse was 136, very small, and soft after the operation. The foot of the bed was elevated, the limbs were bandaged over wool, and normal saline enemata, six ounces, with liquid peptonoids and a little brandy, were given every two hours. A hypodermic injection of 5 minims of liquor strychniæ every three hours was ordered later, as his pulse appeared to be weaker. He gradually improved after this, though very anæmic. The vertical incision healed by first intention; the oblique one healed gradually and not completely till the silk ligature (placed distally to the ulcerated portion of the artery) came away on Nov. 14th. He was discharged convalescent about a month later.

NOTES ON A CASE OF STRANGULATED LEFT DUODENAL (RETROPERITONEAL) HERNIA SUCCESSFULLY RELIEVED BY OPERATION.

BY PRIESTLEY LEECH, M.D., B.S. LOND., F.R.C.S. ENG.,
HONORARY SURGEON TO THE ROYAL HALIFAX INFIRMARY.

THE notes of this somewhat interesting case are as follows.

I first saw the case at 3 A.M. on July 15th, 1902, with Mr. J. A. Marsden of Lightcliffe. The patient was a finely built young fellow, aged 26 years, some six feet in height and very muscular. He had been playing in a cricket match on the 12th, and in the evening he had had a very hearty supper of beefsteak and peas. In the early morning of the 13th he was awakened by severe pain across the abdomen, vomiting following, and he could not get any action of his bowels. Mr. Marsden had attended him for a similar attack in the early part of April, 1902, and relief had been obtained by calomel; the patient had also had an attack in the beginning of the same year when the bowels had refused to act for two days. Neither of these attacks was so severe as the present one, the pain and vomiting being much more severe. The pain was very intense, became worse at intervals, and was only partially relieved by morphia. At 3 A.M., when I saw him, he was pretty deeply under the influence of morphia and complained even then of the pain coming on in spasms. He had passed neither flatus nor fæces since the 13th; the vomit had no fæcal smell, but was darkish brown in colour such as often precedes stercoraceous vomiting; the pulse was good and not quickened. The abdomen was moderately distended all over, but there seemed occasionally to be a more pronounced distension localised to an area in the middle of the abdomen and this localised distension and some peristalsis were more marked when the attacks of pain came on as if the distension and pain were due to local spasm of the intestine. The abdominal wall was somewhat rigid, but there was no marked abdominal tenderness. The temperature was normal; enemata had been given without effect. A diagnosis of probable intestinal obstruction was made and it was decided that if he were no better in a few hours operation should be strongly recommended. He was seen again about noon on the 15th. Turpentine and castor oil enemata had been given without avail and the last vomit was distinctly fæcal. Laparotomy was recommended and agreed to, no decision being come to as to the cause of the obstruction.

The abdomen was opened on the same afternoon and before opening it the localised distension before mentioned was more distinctly marked owing to relaxation of the abdominal muscles by the anæsthetic. This distension covered an oval area some seven or eight inches long by four or five broad; the long axis of the oval was placed somewhat obliquely from right to left across the middle line, the upper pole being to the right of the middle line below the liver. On opening the abdomen and pulling aside the omentum the small intestine was seen to be moving behind the mesentery and a diagnosis of retroperitoneal hernia was made. The opening of the hernial sac could not be felt, so the incision was enlarged upwards when it was found that a good portion of the small intestine was contained in a sac behind the mesentery; the mouth of the sac looked obliquely upwards and to the right with a slight forward inclination, the anterior and lower margin being thickened and arched. The finger was passed inside the sac and about a yard of intestine was withdrawn; the abdomen was then sewn up The patient progressed without a single bad symptom and the stitches were removed on the twelfth day, but on the thirteenth day after a severe sneeze the patient felt something give way and on removing the dressing it was seen that the skin wound had been torn open except the upper two inches of the incision, the muscles being exposed. Chloroform was given and the wound was sewn together with a curved Hagedorn needle. Some suppuration took place and about a week later the patient complained of occasionally feeling what he described as a "puffer" going off under the dressings; two or three days later it was discovered that there was a small intestinal fistula which discharged wind and a small quantity of bile-stained fluid at intervals. Whether this was caused by the needle in the second sewing having perforated the small intestine or not I *cannot say, but this seems the most likely explanation.* The patient is now in good health and has had no further attacks of pain.

With regard to the diagnosis of the condition before operation I think a fairly accurate diagnosis might have been made had the condition of retroperitoneal hernia been borne in mind; to assist the diagnosis there were the history of two previous attacks of partial obstruction, the presence of a more or less central tumour, and the paroxysmal character of the pain; these would certainly suggest retroperitoneal hernia as the cause of the obstruction. Another point to which I should like to draw attention is the exact cause of the obstruction in these herniæ. Treves[1] says that when strangulation occurs it is always produced by the margins of the orifice of the sac. In this case it was not the orifice of the sac which was causing the strangulation, for the finger and thumb were introduced without much difficulty into the orifice and the intestine was fairly easily withdrawn, nor were there any marks of strangulation on the bowel. That the obstruction was due to volvulus or twisting of the bowel admits of no doubt. The sac in retroperitoneal hernia is a congenital condition and probably always contains more or less intestine; should the amount of intestine in the sac become increased and distended or should the intestine usually contained in the sac become more distended from some indiscretion in diet increased peristalsis occurs and twisting may easily take place leading to obstruction. Knaggs[2] has drawn attention to the occurrence of volvulus in hernia as a factor in causing obstruction and Moynihan[3] mentions that volvulus has been found in retroperitoneal herniæ. As the inferior mesenteric vein lies in the neck of the sac one would hesitate to cut the margin and for the same reason I did not make any attempt to close or to obliterate the mouth of the sac. Lastly, there is the question of nomenclature. Treves[4] gives some seven names for this hernia and too many names lead to confusion. It would be a gain if these herniæ clinically were called right and left duodenal hernia, leaving to the anatomists any discussion as to the exact fossa which forms the sac of the hernia. Moynihan[5] says the left duodenal hernia is in the fossa of Landzert and not in the fossa duodeno-jejunalis. However this may be, I think it would be a distinct advantage if the terms right and left duodenal hernia were applied to these cases. The left duodenal herniæ are much more common than the right duodenal herniæ.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

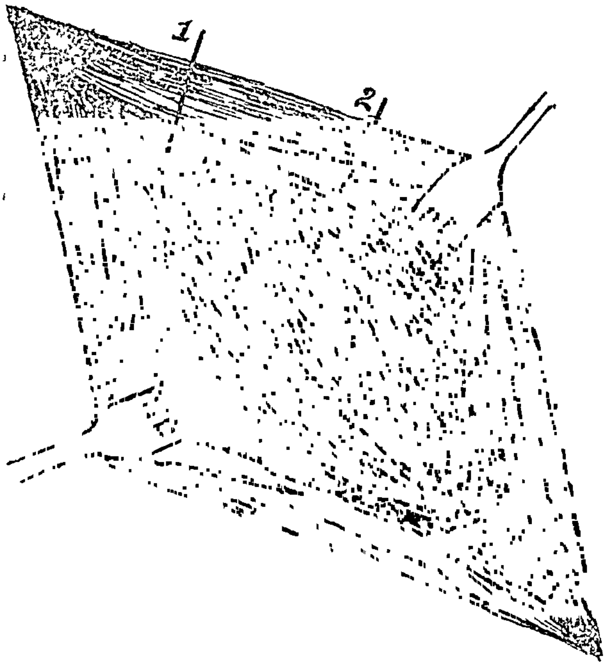
A CASE OF DOUBLE CONGENITAL HERNIA, WITH HERNIA OF THE BLADDER ON THE RIGHT SIDE AND HERNIA OF THE CÆCUM AND APPENDIX ON THE LEFT SIDE.

(Under the care of Mr. H. STANSFIELD COLLIER.)

FOR the notes of the case we are indebted to Dr. H. Y. Taylor, late house surgeon.

The patient, a boy, aged two years, fat and healthy-looking, was admitted to the Hospital for Sick Children, Great Ormond-street, for "double rupture." The following is a brief history of the case. There was no evidence of hernia at birth. A swelling in the left groin was first noticed when the child was six weeks old. The swelling was then of the size of a marble but gradually increased in size and at the end of a month it reached to the scrotum. At the age of five months a similar swelling appeared in the right groin and gradually increased in size until it reached to the scrotum. Various forms of trusses were applied by the medical attendant but were of little use. Between the age of six and eighteen months the child had occasional attacks of "colic" lasting for four or five hours. On these occasions the scrotum became more distended and tender to touch. The herniæ had never been irreducible and there had been little or no constipation. There had been no difficulty in passing urine nor had anything abnormal been noticed in regard to micturition. On admission the child was found to have a very large double hernia filling up the inguinal canal and scrotum on each side. Both herniæ were easily reducible. There was a slight phimosis but urine was passed readily enough. The bowels were regular and the general health was excellent.

FIG. 1.



1, Bladder. 2, Sac and contents.

At Mr. Collier's request Dr. Taylor operated on the right-sided hernia. It was found to be a congenital hernia, the sac containing small intestine. The sac was dissected out and the contained bowel pushed up into the abdomen. There was difficulty in separating the sac from the surrounding tissues, as the former was very thin and tore readily. There was then found to be an apparent thickening of the sac at its upper end extending from the neck of the sac for three-quarters of an inch along its inner aspect. On examination this proved to be due to a para-peritoneal hernia of a portion of the bladder (Fig. 1). This was not closely adherent to the sac and was easily loosened from the tissues in which it was lying and pushed gently back into the abdomen. The sac was then ligatured, the pillars of the ring were brought together by silkworm gut stitches, and the operation was completed in the ordinary way. The child made a straightforward recovery. It is important to note that there had been nothing in the history of the case or in the local condition to lead one to suspect before operating that there was a hernia of the bladder.

Three weeks after the first operation Mr. Collier operated on the left-sided hernia. The sac was exposed and opened and the contents were found to consist of cæcum, appendix, an inch of ascending colon, and two inches of ileum (Fig. 2). The appendix was quite healthy and two inches long. The contents were pushed back into the abdomen, the sac was ligatured, and the operation was completed. Recovery was straightforward. Two weeks afterwards circumcision was performed and a week later the boy was discharged well.

Sac laid open showing contents.

WATTON COTTAGE HOSPITAL.

A CASE OF CHRONIC ULCERATION OF THE STOMACH COMPLICATED BY HAIR-BALL.

(Under the care of Dr. H. MALLINS.)

A WOMAN, aged 22 years, was admitted into the Watton Cottage Hospital on April 12th, 1902, suffering from gastric symptoms. With regard to her previous history the patient, though of weak intellect, had worked as a domestic servant since the age of 15 years. She seemed to have enjoyed fairly good health until the last two years when indigestion troubles began. In October, 1901, she was obliged to leave her situation owing to frequent attacks of sickness and pain after food. Shortly before her admission she vomited a small quantity of blood. A brother had died from acute pulmonary tuberculosis about ten years previously; with that exception the family history was good.

On admission the patient was found to be extremely emaciated and anæmic. The pulse was weak and the temperature was subnormal. The patient's chief complaint was of pain in the left side of the abdomen below the ribs and sickness. On examining the abdomen a large tumour of somewhat rounded outline the area of which could be covered by an ordinary soup plate, was at once perceptible. By palpation and percussion its outline could be traced from the tip of the ensiform cartilage to a transverse line running two inches below the umbilicus. Its right edge, which was the most prominent, could be felt extending into the hypochondriac region about two and a half inches *from the middle line*. The left margin was ill defined and its percussion dulness seemed to merge into that of the spleen. The tumour was very firm on pressure and quite free from tenderness with the exception of its extreme left margin. It could be easily caught between both hands and moved *from side to side*. *No pain except after food* was complained of, and this was never excessive and was invariably relieved by vomiting, which as a rule occurred some hours after food. All the other organs of the body seemed to be healthy. The abdominal measurement over the most prominent part of the tumour was 24 inches. A soda and bismuth mixture was prescribed and a milk diet. Normal menstruation occurred on April 17th. On May 12th the patient's condition was as follows. There was no change in the *tumour*. The vomiting continued as before. It generally occurred during the night some three or six hours after the last food partaken of. This food returned in a pulpy mass with very little moisture. The bowels acted regularly but the stools were very offensive. On August 23rd there had been no change since the last report except an increase of the emaciation and weakness. Slight œdema of the ankles was noticeable. On Sept. 1st the abdomen was more distended and measured 26 inches over the tumour. There was a tendency to diarrhœa, three or four offensive stools being passed daily. The œdema of the legs had increased. The skin surface was nearly always cold and the pulse was almost imperceptible. On Oct. 14th the patient died at 7.30 P.M.

Necropsy.—At the post-mortem examination on opening the abdominal cavity it was at once apparent that the tumour observed during life was the much distended stomach which filled the upper part of the abdomen. Its lower border was firmly adherent to the transverse colon. There was also a slight adhesion between its cardiac end and the parietal peritoneum in the vicinity of the spleen. The general outline of the stomach might be compared to that of a large U shaped tube placed horizontally, the upper limb by far the bulkier of the two comprising the cardiac end and middle third, and the lower and much narrower limb being constituted by the pyloric end and the upper four inches of the duodenum. On opening the stomach its distending contents were seen to be a mass of black hair (weighing 1 pound 9 ounces) reaching from the cardiac end *completely filling its cavity and extending* through the dilated pylorus into the duodenum. On removal of this hairy mass the walls of the stomach were found to be much thickened and the seat of several large chronic ulcers. The largest of these was situated on the greater curvature, at the junction of the middle and pyloric thirds being oval in outline and measuring 3½ inches by 2 inches. Its floor was *formed entirely by the thickened wall of the transverse colon*. The edges of the ulcer were rolled inwards and undermined by the contraction of the fibrous tissue. In its vicinity there was a discoloured patch of mucous membrane marked with black striæ. This presumably was the spot on which the heaviest end of the hairy mass rested its black hue being due to the colouring matter of the hair. Two smaller rounded ulcers were seen on either side of the smaller curvature near the cardiac orifice. *One of them had perforated the gastric wall and its floor was formed* by the adherent pancreas; the other was still bounded by the serous coat of the stomach. In addition to these ulcers the scars of two more that had healed were noticed on the anterior wall and some three or four small but deep excavations in the vicinity of the concave border. All the other abdominal viscera were found to be healthy.

Remarks by Dr. MALINS.—The different views of the nature of the tumour taken during life—viz., retroperitoneal sarcoma, pancreatic cyst, and tuberculous enlargement of glands—are seen in the light of the necropsy to have been incorrect. The expediency of an exploratory operation was several times discussed but the extremely feeble state of the circulation was considered to be prohibitive. Had such an operation been attempted it is extremely doubtful if recovery would have taken place in view, of the very unhealthy condition of the stomach walls. An interesting question arises in connexion with the case—viz., did the hairy mass produce the ulcers by its pressure or was their origin distinct? I am disposed to take the latter view, chiefly owing to the fact noticed at the post-mortem examination that at the point where, judging from the staining of the gastric wall the chief weight of the mass impinged there was no breach of surface. It is not improbable that the ulcers produced *a morbid craving which led to such an* unnatural method of trying to appease it. The case teaches two lessons: (1) in tumours of the gastric region the possibility of hair ball distension should not be overlooked; and (2) in all doubtful cases where the patient's strength is equal to it an exploratory operation should not be omitted.

Medical Societies.

EDINBURGH MEDICO CHIRURGICAL SOCIETY.

Exhibition of Cases.

A MEETING of this society, which partook of the nature of a clinical demonstration was held recently under the chairmanship first of Sir T. R. FRASER and then of Dr. O. W. UNDERHILL.

Mr. ALEXANDER MILES showed a patient who illustrated the *Comparative Results of Chopart's and Syme's Amputations*. Both feet were cut off as a result of an accident on the railway and the right ankle showed that with Chopart's operation there was a greater width given to the extremity with resulting benefit in walking. As regarded the adaptation of artificial limbs the patient stated that the left ankle with Syme's stump was the more comfortable of the two.

Mr. MILES also showed four patients who had been operated upon for Perforated Duodenal Ulcer. The first was a female aged 21 years, who had been operated upon three years previously. There was no antecedent history of ulceration of the stomach or *duodenum*. A week before her admission to hospital she had complained of slight pain in the right hypochondrial region. This passed off, but just before her admission it had occurred with great severity and she soon became collapsed. On admission her pulse was 94 and her temperature was 99° F.; the liver dulness was completely lost. The operation was performed 20 hours subsequent to the rupture and consisted in cutting through the right rectus muscle and so getting *access to the duodenum in the first part of* which a perforated ulcer was situated. Fluid was present in the *pouch of Douglas*. The second case occurred in a *man* aged 52 years, who was suddenly seized with intense abdominal pain; there was no loss of liver dulness in this case. Under the right lobe of the liver there was an area of extreme tenderness and the maximum degree of pain was elicited here. There was no distinct fulness palpable. The operation was performed four hours after the arrest of severe *symptoms*. *On opening* the abdomen there was an escape of bile stained fluid and white flocculi resembling curdled milk. No fluid was present in the recto-vesical pouch. A drain was inserted over the pubes. The third patient was a man aged 39 years. On Oct. 25th, 1901, he had been doing hard work which necessitated his climbing over or under fences and on returning home he partook of a hearty supper. At 11.30 P.M. he was suddenly *seized* with intense abdominal pain. The operation was performed 15 hours after the perforation and was followed by a good recovery. The fourth patient was a man, aged 26 years who had been operated on five years before. He had previously suffered from dilatation of the stomach and had occasionally to wash it out. While at work he was suddenly seized with intense pain. The operation was performed two hours after the rupture. The right rectus was cut obliquely across so as to allow of better access to the duodenum which it certainly did, but the difficulty in suturing the muscle was so great that Mr. Miles had never repeated this oblique incision. The patient was fed on the fifth day by the mouth. He occasionally has to wash out his stomach but is otherwise in perfect health. Mr. Miles said that he had operated on four other patients for similar disease but unsuccessfully; in three of them the intervals between rupture and operation were respectively 18½, 60, and 54 hours; in the fourth the interval could not be ascertained. This gave an operation recovery of 50 per cent.

Mr. C W. CATHCART showed the following cases for Mr. F. M. CAIRD:—1. A woman after removal of a Gastric Carcinoma. She was operated upon on June 7th, 1902. A large mass grew from the stomach and was so adherent to the colon that it could not be separated. Six inches of the transverse colon and one-third of the stomach were removed and the patient was now in excellent health. 2. A woman who had suddenly been seized with acute abdominal pain simulating acute appendicitis. At the operation the gall bladder was found to be gangrenous and contained a calculus. These were removed and the patient is now well.

Mr. CATHCART also showed the following cases:—1. A man on whom laminectomy for paraplegia had been performed. After Dr. MacEwan had introduced the operation it was at first thought that all such cases of paralysis due to spinal disease could be cured by laminectomy, but it was soon found that only a small proportion could thus be benefited. The disease in this case was situated about the eleventh or twelfth dorsal vertebra and caused complete sensory and motor paralysis. On removing the prominent laminæ the dura mater was found to be in close contact with them and the spinal cord appeared to be compressed. The dura mater was not opened and before the operation was completed the cord had regained its normal appearance. The patient complained of great pain after the operation, but had gone on steadily improving and could now draw up his legs and could locate sensory impressions. The wound was quite healed. The paralysis was complete from July, 1902, to April, 1903 2 A female exhibiting the results of an unusually severe Whitlow. In spite of baths and the local application of ichthyol, the inflammation and swelling ran up the arm and no benefit was obtained from free incisions. In a few days the whole inflamed area suddenly became the seat of purulent foci and abscesses formed in the right shoulder-joint, in the front of the chest, and in the leg. It was decided to amputate at the elbow and for a few days the patient's life was in great danger. A streptococcus was isolated but it did not seem to grow in the usual manner. 3. A patient after short circuiting the small intestine on account of a Fæcal Fistula. 4 A patient in whom Epithelioma had developed on the seat of lupus scars on both sides of the neck.

Dr. ALEXANDER JAMES showed (1) a girl, aged 13 years, who had suffered from so-called Acute Labyrinthitis (Voltolini); and (2) a boy, aged seven years, with similar acute symptoms but associated with Blindness and Optic Nerve Changes. In 1866 Voltolini described this disease as occurring almost entirely in children and as having the symptoms of an acute specific fever, the pain being chiefly in the ears and the back of the head and associated with either insensibility or convulsions. In about a week the patients begin to improve but complain of deafness and giddiness The latter passes off but the deafness remains and is almost always absolute and complete. Voltolini described it as due to acute labyrinthitis and a good many of such cases had been recorded since. It was now, however, more generally believed to be an abortive form of epidemic cerebro-spinal meningitis. The girl was seized with the illness in December, 1902, and complained of fever and severe occipital headache, great pain on moving the head, with stiffness of the muscles of the back. She had almost constant vomiting and became comatose in two or three days. She recovered in about ten days but her hearing was greatly impaired and she soon became completely deaf. The boy was also suddenly seized with sickness, vomiting, and headache. He had been perfectly healthy previously. The right eye first became affected and the pupil was greatly dilated and later the left eye followed. The blindness was almost complete. When admitted to hospital on March 7th he complained of frontal headache; both pupils were widely dilated and did not react to light. Conjugate movements to the right were slightly impaired but there was no definite change in the fundus of the eye. The nasal secretion was examined but no organisms were found. On the 21st he was in good health but distinct evidences of commencing optic nerve atrophy were seen in both eyes. Later the vision began to improve, whilst the optic atrophy advanced. These two cases were both evidently due to the same disease, the toxin in the one case affecting the nuclei of the auditory nerve whilst it affected the nuclei of the optic nerve in the second.

Mr. H. ALEXIS THOMSON exhibited the following cases:—1. A boy after operation for Osseous Ankylosis of the Jaw. He had suffered from a stiff jaw for seven years and it was said to have been initiated by a blow. The ankylosis on the left side had arrested the development of the lower jaw as a whole. The incision was made over the left condyle and the condyle and the greater part of the ramus, as well as the condyloid process had to be removed before free movement could be obtained. There was now complete movement, though the jaw still remained small. 2. Two female patients after Excision of the Shoulder-joint for Tuberculous Disease after the method devised by Kocher. Though two and a half years had elapsed since the excision the movements of the arm in both cases were very restricted. The glenoid cavity and the upper end of the humerus were removed and so absolute ankylosis had resulted and any movements were made through, or restricted by, the shoulder-blade The disease in both cases had been absolutely cured.

Dr. GEORGE A. GIBSON exhibited a male patient suffering from Addison's Disease and presenting an intense degree of pigmentation of the mucous membranes.

Dr. NORMAN WALKER showed a series of cases of Lupus to demonstrate the permanence of cure induced by the x-ray treatment.

EDINBURGH OBSTETRICAL SOCIETY.

Tracheal Compression in an Infant.—Deciduoma Malignum—Cyst of the Labium Minus.

A MEETING of this society was held on May 27th, Dr. JAMES RITCHIE, the President, being in the chair.

Dr. ANGUS MACDONALD read notes on a case of Fatal Tracheal Compression by Enlarged Thyroid in a Newly-born Infant. The infant was born at eight months, about 10 minutes before the medical man arrived. He found the child in an advanced stage of asphyxia, but after performing artificial respiration the breathing became established to some degree; rhythmic traction on the tongue acted most beneficially in producing this result. But the manifest difficulty in the respiration led to a close examination of the neck, when he found the thyroid enlarged, its lateral lobes being of the size of a marble and of firm consistence. The breathing became more laboured, the lower ribs being drawn in with each inspiration, and by four hours after birth the infant was evidently in such a serious condition as to require operation, but death occurred during the performance of tracheotomy. It was noticed that the thyroid was covered with a network of congested veins and that the lobes seemed to swell as the body was more cyanosed. These cases are rare Dr. J. W. Ballantyne had recorded a fœtus between the third and fourth months which exhibited a general congestive enlargement of the tissues of the neck between the lower jaw and the manubrium sterni. A case was recorded by Sir J. Y. Simpson in 1855; the child was the tenth of a non-goitrous woman and on account of the pressure of the goitre died in eight hours. The goitre was as large as a hen's egg and caused forehead presentation Another case was recorded by Keiller in 1855 in which a large irregularly lobulated swelling in the region of the thyroid gland gave trouble by causing forehead presentation. A case was recorded by Dr. A R. Simpson in 1866, when the mother had been taking chlorate of potassium throughout pregnancy for the prevention of miscarriage and premature labour; the thyroid seemed to be equally enlarged in its isthmus and lateral lobes. At first there was difficulty of respiration and deglutition but at the age of four years the tumour was much shrunken and the child appeared healthy. In Dr. Macdonald's case the mother had been taking chlorate of potassium during the pregnancy from the second month; neither parent had any thyroid enlargement.

Dr W. E Fothergill of Manchester had recently had a similar case, and also Dr. J. T Hewetson of Birmingham, and in both chlorate of potassium had been administered — Dr J W BALLANTYNE, Dr D BERRY HART, Dr H O NICHOLSON, and the PRESIDENT discussed the paper

Dr J M MUNRO KERR (Glasgow) gave the clinical history of a case of Chorion Epithelioma (Deciduoma Malignum) The patient was 23 years of age and was first seen in May, 1902, suffering from pains in the abdomen and hæmorrhage from the uterus There was a history of miscarriage in September, 1901, and she had been curetted in March, 1902, which was followed by *constant bleeding In May she was extremely anæmic with* a pulse over 130 and her temperature varied from 103° to 105° F The uterus was again curetted and some masses were removed, but these were unfortunately not preserved for examination The temperature fell from 106° to normal in 12 hours after the operation but rose again slightly afterwards During the next month she had a sharp metrorrhagia and the temperature then began to show an evening rise which was considered to be due to sepsis and intra uterine douching was carried out but with no benefit At the end of July she came under Dr Kerr's care and on exploring the uterus with the finger he found a large rough mass towards the fundus which bled very freely As it was evidently a case of deciduoma malignum he removed the uterus but the patient died the same evening A post-mortem examination was refused but during the operation the broad ligaments were freely moveable and no enlarged glands were felt —Dr JOHN H TEACHER (Glasgow) gave a pathological report of the specimen with lantern slides The tumour occupied the fundus and posterior part of the uterus and was of about the size of a five shilling piece ; it was covered with mucous membrane partly ulcerated Microscopically it showed the typical structure of a chorion epithelioma but with an unusual amount of the cells which are regarded as transition forms between the Langerhans layer of the tumour and the syncytium —Dr F W N HAULTAIN, Dr BERRY HART, and Dr BALLANTYNE discussed these papers

[illegible] f Cyst of the
L [illegible] unmarried,
a [illegible] symptoms
She had noticed a small growth in the vulva for at least three years; it was painless, caused no symptoms, and had not increased in size during the last 18 months Its presence caused her much anxiety *It was situated in the posterior* third of the left labium minus or more correctly in the interlabial sulcus with its main portion in the labium minus , it measured three quarters of an inch by half an inch, had a bluish cystic surface, and was freely moveable It was not painful but on account of the mental worry it produced it was deemed advisable to remove it On incision clear serous fluid escaped and the cyst was found to be incompletely filled with a papillary growth which had all the macroscopic appearances of an ovarian papillary cystoma There had been no recurrence after its removal last September The general health improved very much after its removal — *Dr BERRY HART made remarks on the paper*

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on May 21st, Dr W Winslow Hall, the President, being in the chair —Dr E Laming Evans showed an infant with Swelling of the Right Foot. The swelling involved the four outer toes and the dorsal and plantar surfaces of the foot to the level of the bases of the metatarsals and was for the most part firm and solid The three middle toes were webbed and there was increase in the circumference of the leg and of the right buttock The thigh appeared to be normal A skiagram showed that the phalanges of the four outer toes were expanded, that the second and the third were irregularly placed, and that the third phalanges of the third and fourth toes were conjoined The rest of the bones were normal Probably the case was one of congenital hypertrophy involving vessels, nerves, bones, muscles, and fibrous tissues, the chief characteristic being hyperplasia of the subcutaneous tissue with special involvement of the lymphatics Other possibilities were fibrochondroma or nævo lipoma The treatment suggested was dissection of the growth from the dorsal and plantar surfaces *with removal of the fifth metatarsal bone* and all the phalanges, leaving the great toe intact —Mr Francis Jaffrey thought the case likely to be one of nævolipoma.—Mr. T. Crisp English considered that the child was suffering from congenital hypertrophy, especially as the calf and buttock on the same side were also hypertrophied —Mr English showed a girl, aged five years, with a Congenital Facial Cleft An operation had been previously performed but no further particulars could be obtained The cleft extended from the right side of the upper lip to the inner canthus The right side of the nose and the right nostril were completely absent and the palate was very highly arched [illegible]
ance by a plastic [illegible]
was discussed —M [illegible]
30 years, suffering from a large Desmoid or Fibrous *Tumour of the Abdominal and Thoracic Walls* The patient had had one child The tumour had existed for eight years and at the present time occupied the greater part of the anterior abdominal wall and extended upwards over the thorax, involving the left breast.—Dr Alexander Morison showed a case of Mitral Valvular Disease with much Hypertrophy of the Heart and probably adherent pericardium, in which he considered that the chief mechanical difficulty was the reflux of blood through the auriculo ventricular orifice and some virtual stenosis of the same from enlargement of the ventricular cavity He showed the patient on account of the wide area of audibility of the systolic bruit There was also a palpable thrill The bruit could be heard in the back as low down as the sacrum and in front at the pubes but not in the femoral arteries The second sounds at the base were normal and could at times be heard to reduplicate at the level of the fourth left costal cartilage Sphygmograms showed a well marked aortic notch and cardiograms showed the flat top of systole from a hypertrophied ventricle —Mr Jaffrey showed a man, aged 47 years, with Œsophageal Obstruction There had been difficulty in swallowing for about three months and the patient's condition was becoming worse so that he could *only swallow fluids He asserted* that some ten days previously he vomited a pint of bright blood The day after admission to hospital he brought up seven or eight ounces of bright blood and immediately afterwards he could swallow with greater ease A bougie passed 12 inches and impinged on what appeared to be a hard growth Owing to the bleeding, however, it had been suggested that the obstruction might be due to a leaking aneurysm During a week in hospital the man had increased six pounds in weight No sign of aneurysm was apparent by the x rays Mr Jaffrey considered the case to be one of carcinoma and proposed to perform gastrostomy when the patient's condition became worse

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY—A meeting of this society was held on May 15th, Dr J E Gemmell, the President, being in the chair —Specimens were shown by Dr J B Hellier (Leeds), Dr E O Croft (Leeds) Dr W Walter (Manchester), and Dr D Lloyd Roberts (Manchester) —Dr W McGregor Young (Leeds) read notes of a case of Acute Mercurial Poisoning from Intra uterine Injection The case was of special interest [illegible] of placenta
[illegible] *ill more or*
[illegible] tion of the
placenta after delivery with forceps necessitated manual removal, which was followed by an intra uterine douche of a 1 in 3000 solution of biniodide of mercury followed by one of plain water On the tenth day there set in indications of sepsis and a bit of placenta was removed from the uterus Later the classical symptoms of acute mercurial poisoning became well marked Further exploration of the uterus disclosed another piece of placenta which was removed By the nineteenth day the patient was progressing well, but a recurrence of the mercurial symptoms took place *Ultimately the patient* made a good recovery Salivation and stomatitis were absent throughout, but there were soreness and stiffness of the jaws preventing mastication, severe headache, coppery taste in the mouth and severe purging and tenesmus —The President remarked that solutions made by the dissolving of compressed drugs were apt to be imperfectly mixed if used hurriedly, the solution at the bottom of the vessel being much stronger than that higher up in the same vessel —Dr Croft thought it was unnecessary to advance trauma as the explanation of the symptoms that had been described He agreed with the President's remarks anent the imperfect solution of powders and commented on the difficulties in distinguishing the diarrhœa of sepsis from that due to mercurial poisoning —Professor C J Wright (Leeds) said

that for some years he had used mercurial solutions in no greater strength than 1 in 5000 or 1 in 6000, and then only with the greatest care. He considered that weak boric or carbolic acid solutions were better for intra-uterine use than sterilised water.—Dr. Young, in reply, referred to a paper by Professor C. R. Marshall (St. Andrews) on poisoning by mercurial solutions in obstetric practice.—Dr. A. C. F. Rabagliati (Bradford) read a paper on the Causes and Prevention of Cancer. After a brief review of the principal theories at present before the profession Dr. Rabagliati propounded his own view that cancer is from first to last a disease of over-feeding. He adduced many closely reasoned arguments in support of this theory and indicated the lines of treatment to be followed on its basis.—The President complimented Dr. Rabagliati on this paper and remarked that well-nourished persons were more often attacked by malignant disease than those less well nourished.—Dr. Roberts and Mr. C. Richardson (Leeds) also spoke and Dr. Rabagliati replied.

Bradford Medico-Chirurgical Society.—A meeting of this society was held on May 19th, the President, Dr. H. J. Campbell being in the chair.—Cases and specimens were shown by Dr. Andrew. Little, Mr. J. Basil Hall, Mr. C. F. M. Althorp, and Dr. W. Mitchell.—Dr. Mitchell read notes on two cases of Disease about the Hip-joint The first case was that of a boy, four and a half years old, who had been treated for two years for supposed hip disease. The affected limb was an inch longer than the other. The tissues were swollen about the upper part of the right thigh and there were numerous sinuses leading down to bare bone. The mobility of the hip-joint was much diminished. The sinuses were first treated by injections of biniodide of mercury (1 in 1000) and afterwards of hydrozone. After 18 days of this treatment the patient was much improved in health. Chloroform was then administered and the sinuses were slit up and freely curetted. No disease of the hip-joint was detected; an area of bare bone on the shaft of the femur was chiselled away. The patient did well and all the sinuses were healed in five weeks. The boy was walking well without assistance except that he had a thickened sole for the boot of the *sound* side. Dr. Mitchell remarked on the efficacy of the hydrozone as an injection for foul sinuses; he said that owing to the gas liberated necrotic material was driven forcibly out of the sinuses. The second case was one of hip-joint disease in a woman, aged 42 years. She was suffering from hip-joint disease of three years' standing and was greatly reduced by hectic fever. After preliminary treatment of the sinuses, as in the preceding case, excision of the hip-joint was performed by the posterior incision. The result was good and the patient was walking with a crutch five months after the excision of the hip-joint.—Dr. J. Jason Wood read a paper on the Treatment of Certain Cases of Procidentia Uteri. The treatment was applicable in severe cases of complete procidentia where the woman had passed the child-bearing age; it consisted in removing the uterus by vaginal hysterectomy and, either at the same time or subsequently, performing anterior colporrhaphy together with an extensive repair of the perineum. The treatment was efficient as to result and, while not more dangerous than ventrofixation, was more certain to cure. Hysterectomy alone was not sufficient, though giving much relief to the patient, as the bladder was apt gradually to prolapse again after a time.

Glasgow Obstetrical and Gynæcological Society.—A meeting of this society was held on May 27th, Dr. J. Nigel Stark, the President, being in the chair.—Dr. Robert Jardine showed a Child born by a Breech Presentation who only lived a few hours and who had Various Deformities, External and Internal. The external genitals were those of a male but the penis was impervious and the scrotum was empty. The abdomen contained a large tumour which before death was thought to have been a distended bladder. The tumour was found to be cystic and to contain a turbid mucoid fluid which was devoid of fat but contained many cells similar to the seminal cells which secrete the fluid part of the semen. On either side of the tumour were a tube and ovary. The kidneys were cystic, especially the left. The right kidney had no ureter attached. The child was probably a transverse hermaphrodite.—Dr. A. Louise McIlroy showed, for Dr. Kelly, a large Tumour of the Uterus which had been diagnosed as fibroid complicated with malignant disease of the omentum. On section the whole tumour was found to be attached to the uterus and on microscopic examination part was found to be malignant.—Dr. Carstairs C. Douglas demonstrated Saul's Test for determining whether Milk had been Sterilised or not. The amount of pasteurisation which vitiated the test was noted. The test was considered to depend upon the presence of a ferment in the milk which was destroyed by boiling.—Mr. S. Stuart Nairne read a paper on Menstrual Epilepsy. A number of cases were said to have been so much improved that no fits had been noted during a period of even five years. The treatment advocated was dilatation of the cervix in cases of stenosis, curettage, the application of the actual cautery to the fundus, and removal of the ovaries if diseased.—Dr. Adamson, Dr. Douglas, Dr. MacLennan, and the President discussed the paper, the consensus of opinion being that the epilepsy had nothing to do with the menstrual phenomena and that disease in the pelvis ought to be treated on its own account.

Pathological Society of Manchester.—A meeting of this society was held on May 13th, Dr. J. J. Cox being in the chair.—Professor E. F. Trevelyan of Leeds read a short paper entitled "Some Remarks on Two Cases of Acute Miliary Tuberculosis."—Mr. W. P. Montgomery showed two specimens of Intussusception of Meckel's Diverticulum. In each the infolding of the process had originated an ileo-colic intussusception. The first specimen had already been exhibited a year previously to the Society for the Study of Disease in Children. At that time six or seven cases alone could be found, while during the last few months the number had increased to nearly 20. The decided inference was that many cases were overlooked either at the operation or at the necropsy.—Mr. W. P. Gowland showed (by permission of Mr. D. J. G. Watkins of Lincoln) a specimen of the Uterus, Vagina, and Two Testicles removed from the Scrotum of a Man with symptoms resembling those of Strangulated Hernia. The patient had worn a truss since childhood for a rupture (?). On Feb. 18th he was seized with acute pain in the abdomen associated with vomiting. When admitted to hospital the left half of the scrotum was empty and shrivelled and the external ring was very small. In the right half were two masses diagnosed as testicles. Between these was a third hard mass which was found subsequently to be a uterus from which a long narrow vagina passed into the pelvis without any apparent communication with the bladder or the rectum. The whole was inclosed in a sac containing fluid and no prostate could be felt per rectum.—Mr. Smith mentioned a case of Duodenal Stenosis for which Gastro-enterostomy was performed.—Several preparations were exhibited as card specimens.

British Balneological and Climatological Society.—A general meeting of this society was held at 20, Hanover-square, W., on May 21st, Dr. E. Symes Thompson, the President, being in the chair.—The officers and council for the ensuing session were unanimously elected. The report of the council on the state and prospects of the society was read and adopted.—Dr. George Oliver (Harrogate) gave an address entitled "A Few Jottings in Physiological Medicine," in which he sketched the results of recent inquiry on the effects of digestion, exercise, temperature, and altitude on the arterial, capillary, and venous pressures. He showed that each meal produced a prolonged wave-like disturbance in the arterial and capillary pressures which was traceable for a period of from two and a half to four hours and which persisted through the temporary variations of the blood-pressure induced by other causes, such as exercise, temperature, &c. The response of the circulatory mechanism to thermic variations of the weather was illustrated by daily records of blood-pressure and atmospheric temperature for three months during the past winter. The effects of altitude on the arterial pressure in winter observed during a recent visit to Switzerland were shown to be a lowering of that pressure in the medium altitudes (from 1000 to 4000 feet) and a raising of it in the higher altitudes (from 4000 to 8000 feet), the rise being due to a compensation caused in an increase of the output of the heart and of the arterial tonus —On the same evening the annual dinner was held at the Monico Restaurant, Piccadilly-circus, the chair being taken by the President. Dr. Robert Barnes and Dr. T. Henry Green were guests of the society.

Bridgwater Rural District.—At the meeting of the Bridgwater rural district council held on May 26th it was stated that the Local Government Board had given its sanction to the council's application for a loan of £23,960 for carrying out a water-supply scheme.

Reviews and Notices of Books.

Practical Handbook of the Pathology of the Skin: an Introduction to the Histology, Pathology, and Bacteriology of the Skin, with Special Reference to Technique. By J. M. H. MACLEOD, M.A. St. And., M.D. Aberd., M.R.C.P. Lond., Assistant in the Dermatological Department, Charing Cross Hospital; Physician to the Skin Department, Victoria Hospital for Children. With 8 Coloured and 32 Black-and-white Plates. London: H. K. Lewis. 1903. Demy 8vo, pp. xxiv. + 408. Price 16s. net

THERE is no other tissue or organ of the body in which the onset and course of pathological processes can be seen and felt as they can be in the skin. In this structure we find laid out before us all the various stages and forms of inflammation, and the skin might be much more utilised than is the case at present for the instruction of the student in the elementary and even in the more advanced pathological processes. In the skin, too, we have the combination of an avascular tissue, the epidermis, with one well supplied with blood-vessels, the derma; and by the study of inflammation in the skin the form it takes in avascular as well as in vascular tissues can be clearly seen. The work before us is an attempt—and after careful examination we may say a highly successful attempt—to put before dermatologists, and especially students of dermatology, a handbook which will assist them in carrying out the histological and bacteriological examination of the skin. It gives a very full account of the processes employed in the investigation of the skin both in health and in disease. It does not confine itself to a mere description of the methods used but enters into details as to the appearances of the structures examined and the objects seen. The illustrations are especially deserving of praise; they are clear and distinct and are for the most part due to the graphic skill of the author.

We are so very satisfied with the book that we have not been able to find material for a detailed criticism of the work, but on one or two points we may say a word. Dr. Macleod gives a very good account of the mode of performing "biopsies," or the removal of small portions of skin during life for the purpose of microscopic examination, but he does not mention Piffard's cutisector which is a useful little instrument introduced some 30 years ago. The author refers to "skin punches" as "recently" devised; they were first introduced by Watson in 1878, though not for "biopsies." We must also take exception to the statement that it is "almost universally admitted" that the "psorosperms" of Paget's disease are merely degenerative epithelial changes.

The book will be of great value to the diligent student of dermatology, but even the experienced dermatologist will find it convenient to have it at hand for consultation when dealing with any unusual point in the pathological histology of the skin. We know no other work in any language written on the same lines, though Max Joseph's little work, "Dermatohistologische Technik," is useful, but it covers much less ground and almost limits itself to a list of stains. We congratulate Dr. Macleod on his book, for it is a credit to British dermatology.

Die Neuronenlehre und ihre Anhanger: ein Beitrag zur Lösung des Problems der Beziehungen zwischen Nervenzelle, Faser, und Grau. (The Neuron Theory and its Adherents; a Contribution to the Solution of the Problem of the Relations between Nerve Cell, Fibre, and Grey Matter.) By Dr. FRANZ NISSL, a.o. Professor in Heidelberg. Jena: Gustav Fischer. 1903. Pp. 478, with two plates. Price 12s.

THE "neuron" theory has now held the field for over ten years as the most satisfactory hypothesis to explain and to bring into harmony all the known facts, anatomical, physiological, and pathological, regarding the structure and function of the nervous system. Although it has been almost universally accepted, there have not been wanting histologists who have brought forward from time to time certain new facts of research which, it has been contended, necessitate the rejection, or at least a modification, of the theory as first put forward and defined by Waldeyer. In this way there has grown up a small band of opponents to the neuron theory, among whom are especially to be mentioned Bethe, Apathy, and Nissl. Dr. Nissl is one of the latest recruits to the ranks and in the treatise under review he defends his position and undertakes to controvert all the arguments put forward in defence of the neuron theory by its most notable adherents. The treatise is in consequence of a highly contentious and polemic nature and the author does not spare himself or his readers in his very lengthy dissertations in order to disclose a faulty point of logic in the arguments of his opponents. Instead of choosing the most obvious method of treating the subject by laying his own views clearly and concisely before his readers he makes the champions of the neuron theory the subjects of separate chapters and his own views and opinions are left to show themselves in the course of his discussions. This does not make easy reading, but the author is of opinion that in this way he more clearly discloses the falsity of his opponents' views.

In reviewing the treatise it is not possible to give even a short *résumé* of the many points raised by Dr. Nissl, mostly of a highly technical nature, by which he seeks to overthrow the neuron theory. At the start he defines the theory in the words of Waldeyer: "The nervous system consists of numerous nerve elements anatomically and genetically independent of one another," and he will accept no modification of the theory as laid down by Waldeyer. Following this line of argument he accordingly rejects any attempt to recognise the theory of nerve units in a biological sense (Edinger) or to regard the nerve units as trophic and functional (Hoche), or as embryonic and trophic (Münzer). Dr. Nissl contends that if known anatomical or physiological facts do not harmonise with the view that the nervous system consists of so many independent nerve units or neurons, the neuron theory necessarily falls to the ground. Many of the facts which he brings forward are already sufficiently well known, such as Bethe's experiment on the crab, in which he obtained reflex phenomena after removal by section of all nerve cells involved in the reflex path. Apathy has already shown by his work on annelids that, at least for certain invertebrates, the neuron theory can no longer be maintained. Dr. Nissl admits that our ignorance of the actual connexions and relations between nerve cell, nerve fibre, and the grey matter prohibits our applying the results of Apathy's work to vertebrates, but he is disposed to believe that an analogous condition exists. He maintains that we are quite in the dark as to the constitution of the grey matter of the cortex and he believes that it contains in addition to nerve cells, neuroglia, and blood vessels, certain nerve elements the nature of which is at present unknown to us. Much of the book is taken up with histological details in regard to the structure of the nerve cell, the fibrils, and the pericellular network and their mutual relationship, about which he has much to dispute with Ramon y Cajal and others.

Dr. Nissl is one of the highest authorities on the histology of the nervous system and it will be interesting to follow the effect which his treatise may have upon those working in the same sphere.

LIBRARY TABLE.

Nerves in Disorder. By A. T. SCHOFIELD, M.D. Brux. London: Hodder and Stoughton. 1903. Pp. 202. Price 3s. 6d.—We learn from Dr. Schofield's preface that his book consists mainly of a lecture delivered some twelve years ago at the Sanitary Institute. We are not as a rule enamoured of medical works published for lay people but to do him justice Dr. Schofield makes an apology for the issue of his book, and we think that he is justified. Even nowadays those diseases which for want of a better name we call "functional nerve disorders," though they may not improbably be based upon some minute organic changes in the nervous tissues, are frequently looked upon as "imaginary" and there is no class of disease in which sufferers are so wont to fly to the use of "cures" of various kinds or of some particular form of diet or even to such blatant forms of imposture as Christian Science. Therefore we think that when a patient sees, as he will see if he reads this book, that medical men do recognise that "nerve weakness" is a disease which can be "cured" just as easily as any other disease by means of appropriate treatment, he, or more likely she, will not waste his or her substance upon quackery and his or her remaining stock of health in the pursuit of a phantom. We cannot agree with all Dr. Schofield's statements; for instance, p. 37, "The sensation of pain can be produced as really and vividly by thoughts or ideas alone as light in the eye by striking it." Now this statement requires modification. The pain which the neurasthenic suffers is eminently real and is probably entirely produced from within. But we deny that if an ordinary healthy normal man or woman sits down and thinks of, for instance, a splinter being driven under the nail any sensation of pain will be felt. Again, we think it a pity that Dr. Schofield has given such a copious list (pp. 82 and 83) of all the symptoms which may characterise neuromimesis, for the mere perusal of the list would cause alarm to a nervous patient. But on the whole we fancy that the book may prove of use.

Burdett's Hospitals and Charities, 1903. By Sir HENRY BURDETT, K.C.B. London: The Scientific Press, Limited. Pp. 1020. Price 5*s.*—A very large amount of information is contained in this compact volume. About 450 pages are occupied with lists of the hospitals, asylums, dispensaries, convalescent homes, and nursing institutions of the British Islands and about 100 pages with a similar enumeration of Colonial and Indian hospitals; 14 hospitals are mentioned as situated in our newly acquired South African possessions—the Transvaal and Orange River Colonies. The introductory part of more than 200 pages is divided into 13 chapters treating, among other subjects, of such questions as the general outlook for British hospitals, the administration of a large hospital, hospital construction, nursing, Hospital Sunday Fund, Hospital Saturday Fund, and hospital finance. As a book of reference Sir Henry Burdett's compilation is one of the most useful of its class.

Physics and Chemistry adapted to the Requirements of the First Examination of the Conjoint Board of the Royal Colleges of Physicians and Surgeons and also for General Use. By HERBERT E. CORBIN, B.Sc., L.R.C.P. Lond., M.R.C.S. Eng., and ARCHIBALD M. STEWART, B.Sc. Lond. Second edition. London: J. and A. Churchill. 1903. Pp. 438. Price 6*s.* 6*d.*—The first edition of this book was published in 1899 and was reviewed in THE LANCET of Nov. 4th of that year, p. 1239; the authors state in the preface of the present edition that a few alterations have been made and that a little additional matter has been inserted. It appears that about 14 extra pages of letterpress have been supplied, but, strange to say, no attempt has been made to bring the book up to the standard of the present requirements of the English Conjoint Board. The syllabus now in force for the chemistry and physics section of the first examination of the board expects the candidate to possess a certain amount of knowledge of Light, whilst special reference is there made to secondary batteries. Both of these subjects have escaped attention at the hands of the authors of this text-book. These omissions are the more curious, as the preface distinctly states that "the syllabus of work in physics, in inorganic chemistry, and in organic chemistry issued by the Royal Colleges of Physicians and Surgeons has been fully treated." We notice also that the unfortunate description of starch given in the first edition, where it is distinctly implied that the granules from different plants all possess the same distinctive microscopic appearance, is retained unaltered. The Ruhmkorff induction coil has been treated in a fuller manner than was the case in the previous edition and as a rule the diagrams are good and the information given is clear and concise. We cannot but feel, however, that the value of the book to a student reading for the English Conjoint Board examination would have been greatly enhanced if the syllabus had been more thoroughly dealt with.

Alpine Flora for Tourists and Amateur Botanists. By Dr. JULIUS HOFFMANN. Translated by E. S. BARTON (Mrs. A. Gepp). London: Longmans, Green, and Co. 1903. Pp. 112. Price 7*s.* 6*d.* net.—This translation into English should prove a useful companion to tourists who know but little botany but who wish to be able to identify the various plants which they may come across in the High Alps, whilst the amateur botanist at home may obtain some idea of the richly tinted flora of the Alps by the aid of the 40 plates which the book contains. These plates are reproduced in colours from original water-colour drawings of Alpine flora by Hermann Friese, the number of individual plants figured being 250. With a view of limiting the size of the book only the more important plants of the High Alps are mentioned in the text. Each plant is clearly described and there is a short glossary at the end of the book explaining such botanical terms as it has been found necessary to use for the sake of accurate description. As an aid to the traveller in eliciting information from the country people of the Alpine districts the names of many of the plants mentioned are given in German. The arrangement of the botanical families is based upon the system of De Candolle.

JOURNALS AND MAGAZINES.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., ADAM SEDGWICK, F.R.S., W. F. R. WELDON, F.R.S., and SYDNEY J. HICKSON, F.R.S. New Series, No. 185. Vol. XLVII., Part I. May, 1903. London: J. and A. Churchill. Price 10*s.*—The contents of this number are:—1. A long article by H. J. Hansen of Copenhagen on the Genera and Species of the Order Symphyla. The order includes Scutigerella and Scolopendrella. The author of the article has examined many specimens from Algeria, Cape Colony, Venezuela, Chili, the Brazils, Java, Sumatra, and Japan, and describes 24 species. He is convinced that about 100 species are still undiscovered. Collectors should preserve their specimens in spirit of about 63 per cent. alcoholic strength and at most not exceeding 70 per cent. and the specimens should not be pressed upon so as to become flattened. The article is illustrated by seven plates. 2. On the Body Cavities and Nephridia of the Actinotrocha Larva, by Edwin S. Goodrich, M.A., with two plates. 3. Enteropneusta from Madras, by K. Rammuni Menon, assistant professor, Presidency College, Madras, with a plate. The enteropneusta described by the author were dredged at depths of from six to nine fathoms in mixed sand and mud off the Madras coast and belonged to three species. 4. On the Planktonetta Atlantica Borgert, by G. Herbert Fowler, F.Z.S. This animal is a Phœodarian Radiolarian possessing in addition to the ordinary shell of the Medusetlidæ a hollow skeletal sphere larger than the shell, here termed a float. The mouth of the shell carries eight spined arms and gives origin inwards to a skeletal meshwork across the aperture which serves to connect float and shell and to support the phœnodial complex. A bundle of fine tubes leads from the intracapsular to the extracapsular protoplasm, perforating the capsule and the diaphragm. The float, the diaphragm, and the single bundle of tubes of communication are unparalleled among radiolaria. Two plates accompany the article.

The Field Naturalists' Quarterly. No. VI., vol. II.—Edited by GERALD LEIGHTON, M.D. Edin. London and Edinburgh: William Blackwood and Sons. Price 2*s.* 6*d.*—Each succeeding issue of this interesting quarterly seems to show some improvement upon that of its predecessor. In the present number, which is well illustrated, Mr. E. Kay Robinson, in an article on Birds, solicits help in the compilation of a dictionary of the language of birds, while Mr. F. G. Aflalo writes upon "The Spring Awakening of the Sea." In "Reptile Studies" the editor discusses the question of immunity, the much debated question as to whether the mongoose is immune or not to snake-bite receiving special attention. Mr. E M. Wood deals with the subject of Symbiosis. Among the contents will also be found papers on the White Cattle of Chartley, Staffordshire; Newts in Spring; the Nests and Eggs of Birds; the Great Black Woodpecker; Rambles in the Lincolnshire Wold; and a Naturalist's Rambles in Southern China. The frontispiece is reproduced from a photograph showing four young robins on a bough, but the picture in the copy before us has been spoilt by being pasted to the opposite page. This fault we have noticed before and it is a pity that such an excellent publication should be marred by careless binding.

Dublin Journal of Medical Science.—The original communications in the May number are on the Operative Treatment of Enlarged Prostate, by Sir William Thomson; on the Diagnosis of Perforated Gastric Ulcer, by Mr. R. C B. Maunsell; and on Immunity, by Dr. R. J. Rowlette. The Clinical Report of the Gynæcological Department of the Rotunda Hospital, by Dr. R D. Purefoy, for the year ending Nov. 1st, 1902, also appears in this issue.

HOSPITAL MAGAZINES.

Charing Cross Hospital Gazette for May.—Under the heading of American Quacks we are glad to see that two popular magazines are called to account for publishing in their advertisement columns the mendacious effusions of quacks. Mr. P. L. Daniel commences a paper on the Conservative Treatment of Tuberculosis of Bone and Joints and of Superficial Abscesses.

St. George's Hospital Gazette for May opens with an article on Compound Fractures by Mr. L. Jones in which he states that the results of the treatment of compound fractures at St. George's Hospital during the past three years show a marked improvement. Out of 66 cases admitted only two died (excluding those patients who died from shock within 12 hours of admission). "This percentage of 3 stands out markedly against those of 40, 41·8, and even 79 which were given by various authors in the pre-antiseptic days" In a foot-note to the word stinkle, which occurs in "Kubla Khan," a parody said to have been inspired by a nightmare consequent upon reading about a proposal to remove St. George's Hospital, the ways of the motor car are aptly described. It is as follows:

Cf. nursery rhyme (new style).

Stinkle, stinkle little car!
How I wonder whose you are!
Chucking up the mud and dust
Like a geyser on the bust.

Guy's Hospital Gazette of May 23rd contains a clinical lecture on the Operative Treatment of Gastric Carcinoma by Mr. Charters Symonds and publishes an essay on the Pathology of Chorea to which was awarded the treasurer's prize by the Physical Society of the hospital.

St. Mary's Hospital Gazette for May.—In addition to a paper on Aphasia by Dr. Robert Maguire there is a short but interesting article on Medicine in China by Dr. Arthur Stanley, health officer of Shanghai. "The Chinese Pharmacopœia," says the author, "is the largest in the world." Our national summer game does not seem to be very popular among the students at St. Mary's Hospital, for in the editorial notes of the gazette attention is called to the fact that exactly six men have signified their intention of playing cricket this year.

St. Thomas's Hospital Gazette for May has for its prominent feature "Some Extracts from the Common-Place Book of William Savory, Surgeon and Student of the Borough Hospitals in 1788–89." The picture of the life of this obscure country practitioner in the eighteenth century as depicted by the extracts from his diary and common-place book makes very interesting reading.

Looking Back.

THE LANCET, *SATURDAY*, JUNE 4, 1825.

FOREIGN DEPARTMENT.

ANALYSIS OF FOREIGN MEDICAL JOURNALS.

REVUE MEDICALE—MARS.

The Olfactory Nerve.

M. MAGENDIE has lately reported to the Academy a pathological fact, in confirmation of his former opinion, that the *olfactory nerve* is *not* the *organ of smell.* BECLARD had a man under his care in the Hôpital la Pitié, in whom on dissection the anterior portion of the brain and olfactory nerves were found almost destroyed by ulceration, but who at the same time retained his sense of smell. He took snuff, and was quite capable of distinguishing its various qualities.

Appearance of a Medical Work in Turkey!

A medical work has made its appearance, the only one during 150 years, at Constantinople, it is a folio, of 300 pages, with 56 copper-plate engravings, on anatomy and medicine, entitled, "*Mirat el abd fi teohrih azail,*" by Chani-Zadeh Mehemmed-Ata-Oullah, member of the religious and judicial order of the *Oulema.* The Oulemites fill the offices of ministers of religion, of the laws, of equity, and have always endeavoured to crush the rising genius of the nation. It is not, therefore, a little surprising that a work on anatomy, physiology, medicine, and therapeutics, should be published by one of this fraternity. The substance of the work appears to be a translation from various French works. The author being a Mussulman, what he says on vaccination is very interesting; he gives its history, and insists on the many advantages it has over inoculation; he concludes by giving directions as to its use, and with some of the vaccine virus brought from the village of Aiaz-aga, many thousands have been vaccinated in Turkey.

ST. BARTHOLOMEW'S HOSPITAL.

May 23.—Robert Accam, æt. 74, hale constitution, was admitted into Baldwin's ward, with a rupture of the cornea and protrusion of the iris on the right side, in consequence of a blow from a cricket ball; his pulse was 80, full and strong; headache. Cold cloths were applied, and some purgative medicine given (no local depletion!).

28.—Pulse 85; more natural; tongue covered with a slice of Abernethy's 'leather breeches';* pain in the head subsided; slept well; the eyelids and face tumid and of a livid colour; bowels open.

---

* This is a common expression of Mr. ABERNETHY's, to denote a furred state of the tongue.

THE LANCET.

LONDON: SATURDAY, JUNE 6, 1903.

"Opticians" and Spectacle Prescribing.

We publish to-day two letters, from representative "opticians," demurring more or less to the statements put forth in our leading article in The Lancet of May 9th, p. 1312, with regard to spectacle prescribing. Mr. Aitchison is fearful that some of those statements are "liable to misinterpretation," and he tells us that Young did not discover either astigmatism or the function of accommodation. It is universally admitted among men of science that the credit of discovery is not due to the person who first hints at a thing, but to him who establishes the truth with regard to it, and this is the precise position of Young with regard to accommodation, although no claim of the discovery of the mere fact of the occurrence of some change has ever been made on his behalf. "It is now nearly 60 years," wrote Donders in 1864,[1] "since Thomas Young satisfied himself that the power of accommodation depends upon a change of form in the lens. Nor was he led to this conviction merely by the exclusion of other hypotheses; he adduced reasons which, properly understood, should be taken as positive proofs. As an hypothesis the idea had already existed, but previously to the time of Young it could be considered as little more than a loose assertion, to which no value was to be attached." Young's claim to be the discoverer of astigmatism has, we believe, never before been questioned and Mr. Aitchison certainly does not succeed in questioning it successfully. The version given by Donders[2] is that in relaxation of his eye Young saw in his optometer, held in a horizontal position, the double images of the thread intersect one another at seven inches from the eye, but only at ten inches when in a vertical position. The optician Cary, to whom Young *communicated his discovery*, stated to him that he had before *often* found that near-sighted people distinguished objects more acutely when the glasses suited to them were held in a particular oblique direction before the eye—a manœuvre by which, at least when strong glasses are necessary, a certain degree of astigmatism may be corrected. On this basis Mr. Aitchison says that "Cary knew as much about astigmatism as Young did, particularly when the latter goes on to say, 'The difference is *not in the cornea*, for it exists when the effects of the cornea are removed by immersing the eyes in water.'" What really happened was this, that Cary had observed one of the *effects* of astigmatism in the cases of certain customers, but had not been led by his observation to form even a surmise as to the nature of the condition to which the effect was due. His observation remained wholly barren—so barren, indeed, that long after his time opticians were exercising their ingenuity in the construction of frames capable of holding glasses in oblique positions before the eyes. Mr. Aitchison himself, although an optician, seems to believe that Young was in error in saying that his own astigmatism was not corneal. Mr. Aitchison does not appear to know that the lens of the eye is often astigmatic, and that Young's experiment conclusively proves it to have been so in his case. It is further remarkable that Young seems to have been in no way incommoded by his defect, insomuch that he regarded the malformation of his lens only as a matter of philosophical interest, and had no inducement to design glasses for its relief. When Sir George Airy discovered a similar defect in himself, he, not as an optician but as a mathematician, calculated the curves required for its correction, and ordered lenses which were made for him by the optician Chamblant of Paris. It did not become customary for ophthalmic surgeons to prescribe such glasses until Donders in 1862 by the publication of his treatise, "Astigmatismus und Cylindrische Glaeser," had called general attention to the subject and had arranged with the opticians, Nachet of Paris, and Paetz and Flohr of Berlin, to supply the lenses to all who might require them. The discovery was made by Young in 1793 and remained unfruitful in spite of Cary and other opticians. It was made again by Airy and again remained unfruitful except in his own case, and it was not until Donders undertook the general investigation of refractive errors that astigmatism became understood and the means of relieving it universally accessible. We think the contentions of Mr. Aitchison may be dismissed from further consideration.

Mr. Laurance joins issue with us mainly on a question of words. He says, "All discoveries in optics have been made by opticians, whether medical men also or not is beside the question." Few things are more useful than definitions and we may therefore say that we used the word "optician" as a term of courtesy to indicate a person who was engaged in the sale, or sometimes also in the manufacture, of optical instruments and not to indicate one who was conversant with the physics of light. The latter sense is, no doubt, the more correct, but the former has somewhat usurped its place in common parlance. We challenge Mr. Laurance to name a single discovery relating to the structure, optics, refraction, or employment of the eye which has been made by an "optician" who was not "also a medical man." We further differ by the whole sky from his opinion that any information likely to be obtained by spectacle-sellers in the course of their trade education can ever render them qualified to prescribe spectacles for any defects of vision in which the sufferers might not safely be trusted to choose for themselves. The eye is a living organ as well as an optical instrument. As a living organ it is subject to malformations and diseases of numerous kinds, and its diseases and malformations constantly complicate and are complicated by its optical defects. It is impossible for anyone to deal adequately with the latter who is not able to deal also with the former. The first aim of an ophthalmic surgeon, when he is consulted about a case of defective sight, is to ascertain whether the eye itself be healthy or the subject of disease; and the next is to ascertain whether there be any bodily or constitutional ailment by which it is prejudicially affected. Having thus applied his medical knowledge, and having, by methods of exclusion, come to regard the defect as purely optical, he can then bring his optical knowledge into play and can prescribe spectacles for the relief of a defect which he is not called upon to cure. The so-called "optician" would have to begin at the wrong end, and would be likely, as human nature is constituted, sometimes to place undue reliance alike upon his fancied knowledge and upon the resources of his trade. Mr. AITCHISON makes mention, in more than one passage of his letter, of erroneous views about spectacles which have been entertained, and even published, by medical men who had no special knowledge of the subject. The errors quoted are of old date, and they would dwindle into insignificance before those which would certainly attend upon any systematic attempt on the part of spectacle-sellers to become practitioners in ophthalmology. It is with this attempt that the public are at present threatened. In every locality shops are springing up the proprietors of which hold themselves out, by placards, by affixes, and by advertisements, as being qualified to give advice about the eyes and sight; and we have no alternative but to denounce the whole system as one which rests upon false pretences, and which cannot fail to be followed by disastrous consequences. The new professors, we see, are being directed by the "British Optical Association" to style themselves "optologists," a name which at first sight rather suggests professors of the science of roasting or baking (ὀπτός), but which will none the less be effective in deceiving the public. The association kindly adds that the term "oculist" is nowadays understood to mean a "surgeon who operates." In the medical profession it is usually understood to mean a quack who sails under false colours by using a word which does not assert the possession of a medical qualification; and it is on this ground that qualified ophthalmologists are careful to describe themselves as "ophthalmic surgeons." The ignorance of the public has preserved "oculist," and we shall not be surprised if before long it leads them to describe even medical men as "optologists."

[2] Ibid., p. 456.

Public-house Trusts.

ANY movement which includes among its aims the reduction of the amount of drunkenness within the British Isles has strong claims upon the attention of the medical men of this country. In some form or other the physical and the intellectual evils wrought by the excessive use of alcoholic beverages are continually obtruding themselves upon our notice. Whether we are engaged mostly with hospital practice or with practice among the poorer classes or with practice limited to the ranks of the well-to-do we are unfortunately in each case to an almost equal extent confronted with the vicious influences of alcoholic excess. The aims and methods of the Central Public House Trust Association are doubtless in their broad lines familiar to our readers. The recent issue, however, of the association's second annual report may serve well to bring us to weigh the results hitherto achieved by the association and to consider how far the trust movement merits our support as an effort to lessen the excessive amount of drunkenness in our country. We are aware that persons who belong to what may be termed the extreme temperance party view the trust idea with scant favour. We need not in the present article set about refuting the arguments of the temperance extremist but will content ourselves with commenting upon the matter from the point of view of the average unprejudiced moderate-minded individual. To such a person the trust movement appeals because although it cannot hold out the offer of general national moderation in the use of alcoholic drinks, yet it does offer a readily available practical means of improving the conditions under which such drink is at present sold, and of gradually improving the attitude of the public mind towards the drink question generally.

The Central Public House Trust Association has two main objects. The first of these is practical and is, in short, to acquire public control of the traffic in intoxicating liquors by substituting everywhere for private licensees a public body in the shape of a public-house trust company. The second object is educational, or rather propagandist, and aims at influencing the mind of the general public by means of the public press, by pamphlets, by lectures, and through parliamentary representatives. Considering the short life of the trust movement in this country it must be confessed that the second object, at any rate, bids fair to be well achieved. For few people who read their newspaper can have escaped a general acquaintanceship with the broad principles and aims of the trust movement. Regarding the practical aim of the association we may spend a moment profitably in reviewing the present position of the association as revealed by its second annual report. This contains information relating to 37 trust companies and societies for various counties and localities. It is the object of the trust movement to have a company for every county in England and Wales. There remain at the present time 21 counties without any such company. For the institution of these companies the funds of the trust association are, of course, required, if only to pay for licences granted to the association, and in the past year the demands made upon the association's means have proved greater than the incoming money. Considerable expense is naturally involved in carrying out the propagandist work of any association aiming at a wide influence upon public opinion, and the sum expended on such purposes, under £2000, does not appear excessive when compared with the results achieved. The report suggests that practical progress has been slower than that made in the educational efforts of the association. This is not surprising when it is remembered that practical progress in the objects of the trust infers acquisition of public-house licences. The trust does not desire, of course, to acquire fresh licences unless where a fresh licence is to be granted in any circumstance, in which case the trust naturally desires to acquire the licence rather than to let it fall into private hands. The trust aims at diminishing the number of licences. But the buying up of old licences is a matter that involves considerable time and investigation. In the case of new licences as long a period as 18 months is necessary before the new house can be opened. In the case of the acquisition of existing licences there is greater difficulty in England than there is in Scotland owing to the stronger hold in this country possessed by the system through which public-houses are "tied" to one or other firm of brewers or distillers. The opportunities of acquiring important houses are few, nearly all the best houses being in the hands of the brewers. There are, however, at the present time 70 houses in town and country under trust management and more than twice as many pledged to come into trust hands when existing tenancies expire. For the acquisition of existing licences the association looks largely to land-owners, whether public bodies or private individuals. If land-owners can be impressed with the advantage accruing to those who dwell upon their land by the presence amongst them of well- rather than ill-managed public-houses, then the association may get the support that it looks for.

As the matter stands at present we think that the evidence, both from the report out of which we have made brief extracts and from other sources, points to distinct advantage ensuing from a prevalence of the trust system. We are acquainted with the unfavourable criticism of the results of the Gothenburg system in Sweden and Norway which Mr. MALINS put forward in his evidence before the Royal Commission on the Liquor Licensing Laws. We are not convinced, however, that a similar system in Great Britain need produce similar results. We doubt whether the amount of corruption that crept into the Scandinavian system would prevail in this country. Moreover, the inducements held out to municipalities to make great profits out of their public-houses and to justify themselves by the admirable objects to which such profits were devoted do not prevail under the system advocated by the Central Public House Trust Association to the same extent as they do under the Gothenburg arrangement. All reform in the direction of temperance is beset with the difficulties that hedge any attempt to control a strong though undesirable carnal inclination. Reform to an ideal degree, to the degree of making all men and women in England habitually sober, is not to be achieved at a blow. The Central Public House Trust Association is doing work which should improve the present state of the liquor traffic in this country and should help toward the realisation of that general national sobriety which to-day is unfortunately little more than the dream of the ardent temperance reformer.

Leprosy.

THE importance of a knowledge of the etiology of leprosy can hardly be over-rated. In this country it is true that the disease, though once very prevalent, is now very rarely to be met with and when seen it usually occurs in persons who have contracted it in other parts of the world. In some countries, however, as in Iceland, Norway, India, and China, it is very frequently encountered; and, unhappily, it has appeared in new countries where it had never been known before. In the Hawaiian Islands and Australia it has been found and has occurred to a large extent, appearing synchronously with the advent of immigrants coming from countries where the disease already existed. The problem, therefore, of the etiology of so widespread a disease is surely of the highest importance but although many investigators have examined the question with care the results have not been very satisfactory. There is little doubt that the bacillus lepræ, a micro-organism found in leprous lesions, is the true *causa causans* of the disease; and, indeed, this is now generally admitted, but it must not be forgotten that it has not been possible hitherto satisfactorily to cultivate this bacillus in artificial media and therefore three out of four of KOCH'S postulates cannot be fulfilled. Nevertheless, it may certainly be allowed that the bacillus lepræ is the essential cause of the disease. Even when this admission has been made it cannot be said that the problem of the etiology of the disease has been solved, for it is of as great or even greater importance for us to learn how this bacillus finds entrance into the bodies of those whom it affects. It is now held by very few that the disease is hereditary, for it is certain that healthy children can be born of leprous parents. The theory that the disease is contagious has many supporters; it is true that anyone who dwells in a community of lepers is liable ultimately to contract the disease, but 10, 20, or even 30 years may elapse before it appears and therefore we are almost compelled to believe that the malady does not only spread by mere contagion.

It must be confessed that at the present time we have no exact knowledge of the mode of entrance of the bacillus into the body. Mr. JONATHAN HUTCHINSON has for many years been the chief upholder of the theory that the disease is associated with the ingestion of putrid fish. This theory was first brought forward by him in 1870 and has been supported by its author by a very large amount of evidence, but it has received a very lukewarm welcome from most of those interested in the subject. Still, Mr. HUTCHINSON has done so much for pathology, especially in its clinical aspects, that any theory put forward by him deserves the most careful attention and examination before it is rejected, however much it may be opposed to our preconceived ideas. On the other hand, of course it is unwise to follow blindly a teacher, however eminent, for the history of science shows many instances where distinguished teachers have led their followers out of the right road. In order to obtain further evidence Mr. HUTCHINSON has made journeys to South Africa and to India and he has now on his return from the latter country delivered at the Medical Graduates' College and Polyclinic an address in which he maintained the views which he has advocated so long.[1] At the outset it must be pointed out that Mr. HUTCHINSON'S fish theory does not require the denial of the bacterial origin of the disease, it merely attempts to indicate the precise vehicle by means of which the *materies morbi* enters the body. Mr. HUTCHINSON'S theory was originally founded on a case of leprosy occurring in a sea captain who for nearly 30 years had traded with Barbados; during his stay there, which usually lasted about six weeks, he always lived on his ship and none of the ordinary causes seemed likely to have brought about the disease. Mr. HUTCHINSON was thus led to think that some article of diet might be the cause and further consideration led him to consider that it was probably some form of fish. Further observation has merely

THE LANCET

SPECIAL SUPPLEMENT

IN SUPPORT OF THE

METROPOLITAN HOSPITAL SUNDAY FUND

Published in aid of the Appeal to be made on Sunday, June 14th, 1903.

> "The quality of mercy is not strain'd;
> It droppeth as the gentle rain from heaven
> Upon the place beneath: it is twice bless'd;
> It blesseth him that gives, and him that takes."
> *Merchant of Venice.*

THE Metropolitan Hospital Sunday Fund has entered the fourth decade of its existence and for nearly 20 years we have urged its claims for support in a Special Supplement addressed not so much to our usual readers as to that wide public without whose aid the hospitals could not continue their existence. The mercy which we seek to evoke is not of that kind which Portia sought to obtain from the usurer for his debtor, for the hospitals are not debtors to the public, but we would borrow her words, which we have quoted above, and apply them to the generous kindness of him who in the sympathy of his heart mercifully relieves the sufferings of his fellow men. To us the mercy which "blesseth him that gives and him that takes" is that thoughtful consideration for others which it is the pleasure, if it is also the duty, of all good men and women to practise, which it is their pleasure and again their duty to inculcate in their children. The exercise of such a spirit of kindness may be inseparable, even with the rich, from a certain effort at self-denial. Few can give without feeling that the money given is diverted from some other channel into which it might have flowed, possibly with more immediate gratification to the giver; but should any be slow to deny themselves in a cause where the need is so urgent and where the results are so tangible and so real? What those results are the statistics of hospital work will be found no less eloquent to show than the arguments which we have now so often repeated that many of our readers must be familiar with them. We reiterate our appeal, however, not because the contributors to the Metropolitan Hospital Sunday Fund have lacked generosity in the past or because we have lost confidence in them for the future but because the needs of the hospitals grow yearly greater as the population of London increases, largely through the influx of the labouring classes from the country, and because we therefore must aim at eliciting an increased generosity from an ever-widening circle of contributors. On Hospital Sunday the claims of the hospitals of London for support from all classes of the community are brought before worshippers of every denomination of the Christian religion in their churches and chapels and are not, we know, forgotten by those whose religion calls them to worship on a different day of the week or by those who for various reasons do not attend any place of worship at all. It is a collection made simultaneously from all and contributed to by all without regard to their religious belief or nationality, because those who give are well aware that the hospitals to which they contribute stand open by night and by day to receive Christian or Jew, Briton or foreigner, Londoner or countryman, good or bad, without distinction, only exacting from those admitted the one condition that they stand in need of aid. We had almost said that they are open to poor and rich alike, for though maintained for the poor the hospital does not close its door to the rich man or the rich man's wife or child whom accident and injury urgently calling for immediate aid may bring to its threshold. It is a collection rightly made, therefore, from rich and poor alike, and the offertories in church and chapel welcome the gifts of the poorest, while the special donations recorded in past years from wealthy givers show what an important part the generosity of the wealthy may play in increasing the total of the Fund. It will be observed how often the same names are repeated and we may be permitted to express a hope that fresh ones will appear amongst them when the results for 1903 are published.

The greater part of the Fund, however, each year is contributed by those whose offering is placed anonymously with those of their fellow worshippers in the bag or plate at the churches and chapels of the metropolis and its suburbs, and we would remind all that Hospital Sunday is a special occasion calling for a special effort. It comes but once a year; it is in aid of institutions to the existence of which money is essential, the benefits of which are conferred directly upon the poor, indirectly upon the whole community, and with regard to the beneficence of which no controversy of sect or creed can arise. If, however, we urge upon those who go to church and chapel on Sunday that they should exceed the amount of their usual contributions to the offertory, making an exception in favour of the Hospital Sunday Fund, we would once more remind them that on Hospital Sunday they should bring with them the gifts of those who, for various reasons, will not accompany them. The husband or brother to whom Sunday is a day of rest from the work of the week may spend it in seeking fresh air and healthy exercise in the country, but he should not be allowed to forget that his aid is asked for those to whom Sunday brings no rest from pain and to whom, owing to their poverty, health can only be restored by the aid of the hospital. Cycling and golf have made the

Fund lies before us. It contains the name of every place of worship which held a collection for the Fund in 1902 and we have scanned the list in vain. Surrey, Hertfordshire, Kent, Middlesex, and Essex all contribute but in respect of places more or less suburban, the great majority of them being within a radius of 15 miles from Charing Cross. We have, however, shown that patients find their way to the hospitals of London from such counties as Devonshire and Northamptonshire, Norfolk and Cambridgeshire, not one at a time but in appreciable numbers. The absence of country congregations in such circumstances from the list of the contributors to the Fund is a matter which we commend to their consideration, feeling sure that some among them will feel that it is their duty, as it will also be their pleasure, to prevent the possible suggestion that they are without gratitude for direct benefits received.

There is another point also arising out of the free reception of patients from the country by the metropolitan hospitals which thus nobly carry on their work as the great charitable institutions of the mother city. That they should so receive poor patients from the country we do not question, for it is their duty to heal the poor and we only ask for some proportional return in the way of support from the

country. There are, however, persons who believe that the best way to make all hospitals efficient and solvent would be to support them by rates collected under the sanction of laws passed for that purpose. Let us consider what the result of having rate-supported hospitals only would be upon the free admission of country patients to hospitals in London. The answer is a perfectly simple one. It would put an end to it. It is quite possible, no doubt, that under a system of rate-supported hospitals rules might be framed to permit the patient from the rate-supported hospital in the country to pass to the rate-supported hospital in London, in consideration of duly apportioned payments, but to those who are versed in the ways of local officials, and in the necessary restrictions which limit the exercise of their discretion and delay their actions, we would leave the consideration of how such a system would work in practice. There would have to be presumably in all cases of patients admitted to a hospital, or seeking admission, inquiries, such as are now often necessary under the Poor-law, to discover the original home or most recent domicile of each patient and these inquiries would sometimes lead to disputes on the subject to be settled only by litigation. There would be difficulties arising out of the transfer of patients seriously ill or injured, discussions as to charges for the tending of patients coming from alien districts, and all the questions that auditors are compelled to raise where the lawful expenditure of public moneys is under their scrutiny. On the other hand, the hospitals which in London and throughout the kingdom are supported by voluntary contributions are fettered by no red-tape, and their patients are admitted without being subject to geographical restrictions or being compelled to establish a legal right to the satisfaction of jealous custodians of a local exchequer.

THE TAXATION OF PLEASURE.

Not all, however, of those who neglect the Hospital Sunday Fund would be affected by the institution of a hospital rate. Among those who are not ratepayers there are, no doubt, many who do not give because they have an idea that their help would be insignificant. To these we would say that no help is insignificant, whether it comes in pounds, shillings, or pence. The population of the administrative county of London exceeds 4,500,000. The population of London and its suburbs within a radius of 15 miles from Charing Cross exceeds 6,500,000. If by rich and poor contributing according to their means throughout this vast mass of humanity that has gathered itself in and round the metropolis an amount equal to 6*d*. per head were to be collected the average total of the Hospital Sunday Fund would be more than trebled. The amount suggested may seem excessive. Perhaps it will be long before such universal recognition of the hospitals' need by all classes can be obtained. Is it, however, beyond the limits of possibility? In the sum of the population given women and children are included, the destitute out-of-work, and the "submerged tenth." It must be remembered, however, that every sum of £1000 represents 40,000 sixpences and that every sovereign means 40 sixpences, and every half-crown five. The labourer who on a scanty and precarious wage struggles to support a growing family, who spends nothing

---

[1] In 1884 £4500 was received from the managers of the International Health Exhibition.

[2] In 1885 a special donation of £1000 was received from Dr. James Wakley, Editor of THE LANCET.

[3] In 1886 a further special donation of £1000 was received from Dr. James Wakley.

[4] In 1887 a legacy of £1000 was paid by the executors of the late Dr. James Wakley.

[5] Including legacy of £1003 14*s*. from the executors of the late Mr. Thomas Crouch.

[6] In 1891 donations of £5000 from the late Duke of Cleveland, &c., and £1000 from Sir Savile Crossley, Bart., were received.

[7] In 1892 Sir Savile Crossley gave a further £1000; and a legacy of £105 was paid by the executors of the late Dr. H. E. Price of Brighton

[8] In 1893 Sir Savile Crossley gave a further donation of £1000.

[9] In 1894 a legacy of £5000 (less duty) was paid by the executors of the late Mr. W. J. Whitaker, and Sir Savile Crossley gave a further donation of £1000

[10] In 1895 Messrs. Barnato and Friends gave a donation of £10,000; £3400 was received from the Stock Exchange through Messrs. Pym, [illegible]dett and Harris; Lord Iveagh gave a [illegible] ley gave a further donation of £1000; [illegible]

[11] In 1896 Sir Savile Crossley gave his sixth donation of £1000, and legacies were received from Mr. John Smith of £500 and Mrs. May Evans of £172 9*s*. 4*d*.

[12] In 1897 Sir Savile Crossley gave his seventh donation, amounting this year to £500.

[13] In 1898 Sir Savile Crossley gave his eighth donation, amounting this year to £500.

[14] In 1899 Mr. George Herring gave £10,000; Mr. J. Lane Densham gave £1050; and Sir Savile Crossley gave his ninth donation of £500.

[15] In 1900 Mr. George Herring gave a further donation of £10,000; and Sir Savile Crossley gave his tenth donation of £500. An anonymous donor, "F. H.," gave £1000; and £1090 were received from the estate of the late Thomas King.

[16] In 1901 Mr. George Herring gave a further donation of £10,000, and Sir F. Cook, Bart., M.P., gave a donation of £4000

[17] In 1902 Mr. George Herring gave a further donation amounting to £11,575, and Mr. Charles Morrison gave a donation of £1000.

save on the bare necessaries of life, may not be able to contribute 6*d.* for himself and a similar sum for each of those dependent on him. But what of the more or less independent working-man not so burdened in these days of high wages and cheap necessaries? What of the man or woman who has money to spend on pleasures or small luxuries? Does the pint of beer or the ounce of tobacco, the article of personal adornment, or the visit to a music-hall cost nothing? We do not suggest that these should be given up. We merely point out that 6*d.* or 1*s.* deducted from what is spent on these during 12 months and devoted to the benefit of the hospitals would hardly be remembered in looking back on the year's pleasures or would be recalled with a keener sense of gratification than the other items in the account. Even the errand boy might in such a cause save 6*d.* from what he reserves usually for cigarettes (alas) and penny ices without depriving himself of any wholesome form of enjoyment, if not to the direct benefit of his health. In addressing these, the working man and woman, and the wage-earners of all ages who perhaps cannot, as a rule, afford to give purely for charity and the sake of others, we would remind them that it is to them that the hospital opens its doors in the day of their adversity and we would appeal to their sense of gratitude and of independence. We feel sure that if they reflected upon the subject they would be unwilling to be beholden to charity when in sound health and that they would gladly feel when compelled by necessity to accept hospital aid that they had themselves contributed to place such aid within their own reach. To others in easier financial circumstances the taxation of their pleasures would come even more appropriately. As a nation we spend a good deal on pleasure and to some of us luxuries have grown to be almost necessities. A taste for healthy exercise pervades our young people and the milder forms of athletic amusement are retained by many far beyond middle age. These are not all the monopoly of the wealthier class, although some of them may be The bicycle, for example, like the theatre among sedentary diversions, has its devotees among those of comparatively small means and few confine themselves to one form of amusement only. A twentieth part deducted from the money spent upon amusement during a year by most of us would constitute a sum well worth adding to the offertory on Hospital Sunday. It would considerably exceed the 6*d.* to which we would like to see the amount per head of the population raised, and every 6*d* above the first would be a contribution on behalf of one of those to whom giving at all must be admitted to be impossible. No one would deny amusement to their neighbours, least of all to those who seek it as a recreation after toil. No one grudges them the health which recreation brings, not even those who in their beds in hospital wards long for the day when their own health will return But it is to the hospital alone that these can look for health that means more than amusement to them, and it is to the healthy, the young, and the vigorous that we appeal for a more substantial token of sympathy than a passing thought.

Those who themselves have suffered will know what pain means in whatever surroundings it has to be endured and so will those who have seen those dear to them suffer. These, too, will remember the debt that they owe to the hospitals in respect of the aid which physician or surgeon has afforded them—to the hospitals without which the nurse who tended them could not have acquired her training. The debt which the public owe to the hospitals in respect of the training of nurses is in itself no small one

Among those who otherwise might contribute to the Metropolitan Hospital Sunday Fund there are some, perhaps, who have an idea that although the hospitals assist in the progress of science and although patients may incidentally grow well under hospital treatment who would not otherwise do so, these institutions are really little more than scientific laboratories on a large scale where medical men and nurses receive their training with patients as useful object lessons; that they are not places where human sympathy for suffering, as well as care, is shown, so much as wholesale establishments for the practice of surgery and medicine with the necessary nursing controlled by a cut-and-dried routine. We would ask any who may hold these opinions to read a few letters which we publish below *verbatim et litteratim*, only omitting all names, because they were not written for publication. They were handed to our representative at his request by various sisters in a large hospital standing in a poor and densely crowded neighbourhood, and the spontaneous expressions of gratitude and friendly feeling which they contain need no further comment or introduction from us. Such letters are received daily at hospitals from recently discharged patients and often from those who have left the institution for some time but who still cherish a grateful memory of the kindness bestowed upon them. We could have collected hundreds more without any difficulty. It will be observed that the first speaks of an operation performed in the hospital which enabled the writer to enter and to serve in the Royal Navy.

H.M.S. L—— Devonport, Devon.

DEAR SISTER,—I hope you are quite well as it leaves me at present I am writing to let you know that I have joined the Navy about a mounth ago I am now stationed at Devonport on the L—— for the last 3 weeks I have been on H.M.S. I—— further up the harbour I like the Navy very well I passed alright after the opraition in your ward in —— hospital I shall be up on leave about June or July 24 when I shall come and see you I would be pleased if you would remember me to nurse F—— and the night nurse who was there when I was I think this is all this time.

I remain yours truly

Patient W. G.

I thank you fore all your kindness to me while in the hospital.

Convalesent Home,

——,

May 10th, 1903

DEAR SISTER,—Just these few lines to you I really must apologise to you for not writing to you before now I was very sorry that I could not see you before I went away. But it was very early in the moring wen I went away Dear sister I now take the pleasure in writing these few lines to you as I do now you would like to hear from me Hoping this will find you in the best of health pleace god as this leaves me geting along beautiful and also Hoping these will fine all you patients doing well also please god I am very glad to say that this is a beautiful Convalesent home and it is in a beautif place Close by the seaside I am propły injoying myself down hear I think I have got another three weeks to do down hear and then I do come back again I must tell you that we have got beautiful weather down this way I must tell you that I have been out boat sailing since I have been down hear and it is allright Dear Sister if you pleace give my best regards to all the Nurses for me if you pleace and I wishes to be remember to all the Ward mates also if you pleace So good by to you and god bless you and may god be with you always

I Remain your Inquiring Friend

W.

Hoping to hear from you and also for your patients

——,

Nov. 12th, 1902.

DEAR SISTER,—Just a line to inform you that my Wife Mrs. B—— who is now staying at the —— Convalescent Home is slowly but surely recovering her health I can assure you that I cannot find words to express our hearty thanks for the noble manner in which you and the Nurses under your care have striven to bring her around after her serious operation I am sure the kind words you had spoken to her during her illness has helped her towards her rapid recovery she speaks of nothing but praise for every one in connection with the Hospital and we both sincerely hope that the Hospital will continue to prosper as a blessing to those poor sufferers who needs its help.

With kind regards
I remain sincerly yours
Sister R—— M. B——.

Convalescent Home,
—— ——,
24 of July.

DEAR SISTER,—I was very glad that E. g. arrived safely at the institution and he gave me a sixpence and I thank you with all my heart your the Best friend I have got in London and my time is up and I will Be home next week and I dont no what to do Dear Sister and I will leave It to you you are the only one dear sister that I can depend on

yours sturly,
S T.

and E G sends his Best regard and I give my kind regards to the matron.

TO THE CHILDREN.

All those who have children whom they love and cherish in comfortable homes must at times give a thought to those little ones who are brought up in far different surroundings. Children may do much in collecting for the Metropolitan Hospital Sunday Fund and in bringing the sum received to the Sunday collection. They will perhaps do so the more readily when they are assured that there are little ones to whom a hospital is not a place of pain and suffering at all, but the one bright place that they have ever known in which loving care has been lavished upon them, and which they leave with sorrow and would gladly return to.

In conclusion, we would urge upon all to give liberally and to persuade others to do the same, wherever persuasion may be needed. Last year the Fund reached the fine total of £62,669, but £100,000 were aimed at and this year we shall hope to see an increase. Mr. George Herring, whose princely generosity to the cause of the suffering poor in the past four years is beyond all words of praise, has again repeated his offer of giving £10,000 to the Fund, or one-fourth of the whole amount collected, provided that this does not exceed £100,000. Last year the depression caused by King Edward's severe illness and operation, with the postponement of the Coronation ceremony, lay heavy upon the hearts of the people. This year they see their monarch restored to health, strengthening the friendly terms that bind his nation to others abroad, and performing his arduous duties at home with the energy and activity that have always been characteristic of him. His Majesty's interest in all that affects the welfare of the hospitals, for which he has himself inaugurated the Fund which bears his name, is too well known for us to need to dwell upon it. With their King and their Queen in good health, and in the first summer since their Coronation Londoners are enjoying one of the gayest and most prosperous seasons that they have ever seen. At such a time it is possible that the struggle for existence of the hospitals may be forgotten; to us it would seem to be a time at which more than at all others their needs should be remembered.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

Amounts received and disbursed in the year 1902.

Dr.

Audited and found correct, this 13th day of November, 1902.

(Signed) W. H. PANNELL & Co., *Chartered Accountants*, 13, Basinghall-street, E.C.

*** In the preparation of the voluminous statistics of hospital work which have been here digested and exhibited in collected form (and which have been specially supplied to us in response to our applications, and are quite independent of any returns made to the Metropolitan Hospital Sunday Fund Committee) we have been greatly indebted to a large number of secretaries and other officers of the various medical charities of the metropolis. *To them we desire, as on many previous occasions, to tender our sincere thanks.*—ED. L.

Printed and Published by the REGISTERED PROPRIETORS of THE LANCET, at 423, Strand, W.C., and Nos. 1 and 2, Bedford-street, Strand, adjoining

resulted in confirming this opinion and his visits to South Africa and India were undertaken for the purpose of investigating statements apparently contradictory to this hypothesis.

In one particular Mr. HUTCHINSON has modified his theory. He acknowledges that the disease may be transmitted by "commensalism"—that is to say, leprosy may be communicated by any food when the food has become infected by the leper's hands. At Lahore Mr. HUTCHINSON saw a baker among the out-patients at the hospital whose hands had leprous ulcers on them. In this way infection could doubtlessly take place and children are especially ready to receive food from others, even from infected hands. The three main objections to the fish theory have been that in the first place many persons habitually partake of fish but do not contract leprosy; in the second place, that leprosy occurs in districts where fish is unknown; and, thirdly, that by their religion certain sects are forbidden to eat fish and yet many of their members become leprous. These objections Mr. HUTCHINSON sets himself to answer. The first difficulty he surmounts by saying that it is not all fish that will, in his opinion, cause leprosy but only badly cured fish; it is not the excessive use of fish but the accidental reception of a specific ingredient which brings about the disease. The second objection is at first sight of more importance. Writer after writer has roundly asserted that leprosy is found, and that extensively, in districts where fish does not exist—where, in fact, it is impossible to obtain fish. There were two districts in India in which Mr. HUTCHINSON was informed that no fish was eaten, for no fish existed. These were the Chota Nagpur district and the sub-Himalayan country. Mr. HUTCHINSON was assured by men who had lived in the neighbourhood that in the Chota Nagpur district leprosy was prevalent but no fish was obtainable, yet when he visited this district he found that fish was an article of diet in the leper asylum itself and that many of the patients considered that their leprosy was caused by eating fish. In the markets fish was exposed for sale. In those parts of the sub-Himalayan district which were visited by Mr. HUTCHINSON fish was plentiful. Thus Mr. HUTCHINSON claims that one great objection to the theory falls to the ground. The religious difficulty at first sight seemed to be more formidable, but although Hindus will acknowledge that it would be better from a religious point of view for them to abstain from fish, yet the majority eat fish readily and, in fact, Mr. HUTCHINSON was able to find only one man affected with leprosy who absolutely denied ever having tasted fish and he asserted somewhat naively that his reason for not eating fish was that he did not like the taste of it. There is, however, a very strict religious sect in India, the Jains; they are few in number but they are utterly averse to taking life in any form and therefore it may be accepted that it is extremely unlikely that any Jain would ever eat fish, and Mr. HUTCHINSON was unable to find anyone who knew of a Jain affected with leprosy. In an island named Salsette, near Bombay, leprosy is increasing and it is interesting to note that most of the inhabitants of this island are Roman Catholics and therefore they are in the habit of eating fish very regularly. The objection formed on religious injunctions against fish-eating has been weakened by these investigations of Mr. HUTCHINSON and mere general statements that the religious tenets of a sect forbid the eating of fish cannot be allowed to outweigh the direct evidence that fish is eaten.

There is another point that needs to be considered. In India and many other parts of the world various diseases are confused with leprosy, and chief amongst these, as Mr. HUTCHINSON has shown, is leucoderma; therefore the statement that a person is leprous must not be taken as necessarily true unless we can be certain that the observer was aware of this confusion and competent to diagnose the disease. Syphilis and psoriasis are also frequently confused with leprosy.

A careful examination of Mr. HUTCHINSON'S evidence will convince most people that there is something to be said in favour of his theory. It cannot, however, be held to be proved until the bacillus lepræ has been shown to be present in fish, and stress was laid on this point by Dr. H. RADCLIFFE CROCKER at the adjourned discussion on Mr. HUTCHINSON'S paper. It is not at all improbable that an intermediary host may be necessary, as is the case with many of the intestinal parasites. Nevertheless, though at present the theory is only a theory, it is well worth while for general hygienic reasons to attempt to improve the preservation of the fish eaten in countries where leprosy is prevalent such as India and the chief method to this end is the reduction of the salt duty which militates greatly against its thorough use in the preservation of fish. Whether we accept Mr. HUTCHINSON'S theory or not we must express our admiration of his energy in undertaking journeys of many thousands of miles for the purpose of advancing our knowledge of disease and its cause.

Annotations.

"Ne quid nimis."

THE ROYAL MEDICAL BENEVOLENT COLLEGE.

WE would remind our readers that the twenty-ninth festival dinner of the Royal Medical Benevolent College will be held at the Hotel Cecil on Wednesday, June 10th, at 7 P.M. H.R.H. the Prince of Wales has graciously consented to take the chair and it is to be hoped that he will be supported on this occasion by an influential number of the friends and supporters of the charity in question. We need not plead in many words for support for Epsom College. The members of the medical profession know perfectly well the benefits which this society can give to themselves, their widows, and children. Moreover, the College supplies an admirable education which is open to the children of any man, whether he be medical or not. We will simply add that in England alone there are over 20,000 medical men and that if only each one of these would subscribe 10s per annum to the Royal Medical Benevolent College its present anxieties would be largely lightened and its power for doing good would be very greatly increased.

MIDWIVES AND STILLBORN CHILDREN.

IN THE LANCET of April 25th (at page 1200) and of May 9th (p. 1338) the subject of certificates of stillbirth given by midwives in Manchester was mentioned in connexion with a case investigated by Mr. L. J. Aitken, the then acting coroner. It was shown that at the lowest computation 500 infants must be buried in the Manchester cemeteries as stillborn every year, while Mr. Aitken's calculations put the number as high as 1500, and that, as he said, "we have not a single guarantee that every one of these has not lived." Jessie Donough, aged 32 years, the midwife whose proceedings had been in question, was placed in the dock before the Recorder of Manchester on May 25th and pleaded guilty to making a false statement that a child who was born alive had been stillborn. The child had lived one and a half days. "The Recorder said he hoped the sentence he passed would be a lesson to others and ordered the prisoner to go to prison with hard labour for 12 months." Much credit is due to Mr. Aitken for his investigation into this matter, for the proceedings of unscrupulous midwives may largely influence the rate of infant mortality.

TOILET AMMONIA.

COMPARATIVELY strong solutions of ammonia are commonly sold now for domestic purposes, it may be for the bath or for removing grease stains. We have nothing to say against their employment for either object and certainly the use of a few drops of ammonia in the bath is harmless while it is both invigorating and cleansing. It must be remembered, however, that ammonia gas is after all a poison, strong ammonia vapour being fatal to both animal and vegetable life. In most cases the examples of poisoning by ammonia vapour that appear in toxicological records have been the result of an accident. Thus the ammonia bottle has been injudiciously applied to the nostrils of persons in the throes of an epileptic fit and death has resulted. There is also an instance on record of poisonous effects resulting from the breaking of a bottle of ammonia and the sudden evolution of the powerful gas from the spilt liquid. In the bath-room such an accident might easily happen and the public should be enjoined to use the liquid with great care. A spilt bottle of ammonia in the bath-room might easily cause serious shock. A warning, it seems to us, should be printed on the labels of all bottles containing ammonia for domestic purposes, that the vapour is poisonous in large quantities and that special care should therefore be exercised to prevent the wholesale escape of the contents.

THE MEDICAL PROFESSION AND ST. LUKE'S DAY.

A CORRESPONDENT writes to remind us of the fact that this year St. Luke's Day, Oct. 18th, falls on a Sunday. He refers to the fact that the annual service which is held in St. Paul's Cathedral under the auspices of the Guild of St. Luke and also the special services which have been held in Liverpool on or near the same date afford an opportunity of combined worship as a profession to the medical men of London and of Liverpool. He goes on to ask, "Is it too much to hope that the example set by London and Liverpool may be followed this year in other towns and cities?" He points out that St. Luke's Day falls in what may be called "the medical month," when medical schools and medical societies commence their winter session. Most medical practitioners also are at home, having returned from their well-earned holiday, and to many of them life is a round of wearisome duty with little to brighten it, while the efforts which they have to make to earn a livelihood are becoming more difficult every year. It is well, therefore, continues our correspondent, that every member of the medical profession should periodically be reminded of the Divine Exerciser of the healing art, of Luke the beloved physician, and of the respect in which members of the medical profession are held by the clergy. He goes on to point out that services such as these offer an opportunity to members of the medical profession who cannot afford a guinea to subscribe some smaller sum to medical missions or to the benevolent societies of the profession. We think that our correspondent's idea is a good one. The meeting together of the members of the medical profession in common worship is an additional bond of union between men who are, or should be, actuated by one idea—viz., to benefit their fellow creatures by the exercise of their skill. We do not for one instant imply that a medical men should exercise his profession purely for the love of his fellows, for in the medical profession no less than in any other the labourer is worthy of his hire, but in the large towns of this land the carrying out of the suggestion of our correspondent would, we think, work for the good both of medical men and of their patients.

THE FIRE AT ETON COLLEGE.

THE terrible disaster which has cast a gloom over that great school which was about to celebrate its yearly festival was apparently due to one of those heart-rending calamities of which no definite explanation can be given. The house in which the fire broke out was old and irregularly built but no evidence was adduced at the inquest to show in which room the fire originated, neither has the cause of the fire been ascertained. The saddest point in the story is the apparently indisputable fact that the boy Horne's life would have been saved had not the windows of his room been barred, but in Lawson's case death seems to have overtaken him in his sleep. It is, however, comforting to think that both deaths were due to suffocation and not to shock by fire. With the recommendation of the jury as to the removal of all bars from windows we most thoroughly agree. If any protection is necessary for disciplinary or other purposes it seems to us that wire-netting such as is used for rabbit-fencing would answer every purpose. Such netting could easily be cut or broken on emergencies and would be quite strong enough to prevent any boy getting out of his window, either purposely or in a state of somnambulism, which condition has always to be thought of. The window of Horne's room opened on to a balcony over a bay window and a fall from this would at any rate cause serious injury. That two young lives should have been thus prematurely cut off is sad in the extreme and we can but offer our sympathy to the parents of the dead, quorum animabus propicietur Deus, to Mr. Kindersley the house-master, and to the school as a whole upon the calamity which has darkened the summer half of 1903.

THE DISTRIBUTION OF PLAGUE.

As regards Cape Colony the acting medical officer of health states that for the week ending May 9th the condition of the various places mentioned below was as follows. At the quarantine station, Saldanha Bay, 2 Asiatic males remained under treatment in the hospital, both being convalescent. At Port Elizabeth 5 cases of plague were discovered—namely, 1 European female on May 3rd, 1 native male (found dead) on the 4th, 1 European male on the 5th, 1 native male (found dead) on the 7th, and 1 European male (found dead) on the 9th. At the Plague Hospital, Port Elizabeth, 2 native males were discharged recovered, leaving 13 cases under treatment. Plague-infected rats continued to be found in the town during the week. At East London 4 cases of plague were discovered—namely, 1 native male (found dead) on May 5th, 1 native male on the 6th, 1 European male on the 7th, and 1 native male on the 9th. At the Plague Hospital 1 European male died during the week and 1 native male was discharged recovered, leaving two cases under treatment. (Note.—Owing to a telegraphic error 2 cases instead of 1 were shown in the report for the week ending May 2nd as having been admitted to hospital. The native male discovered on April 30th was the only case admitted to hospital during the week. 1 patient remained in hospital under treatment at the end of the week.) At King William's Town 3 cases of plague were discovered, namely, 1 native male (found dead) on May 3rd, 1 European female on the 7th, and 1 native male on the 9th. At the Plague Hospital 1 European female died during the week, leaving 6 cases under treatment. At Graaff-Reinet no cases of plague and no plague-infected rats were discovered. At Burghersdorp 1 plague-infected rodent was discovered. At Queenstown plague-infected rats were discovered on the railway station premises. As regards the Mauritius a telegram from the Governor received at the Colonial Office on May 29th states that for the week ending May 28th there was 1 fatal case of plague.

THE WORK OF THE IMPERIAL INSTITUTE.

FOR ten years we have waited for some evidence that the Imperial Institute would justify its existence. We have watched the fading of that "regally gorgeous" colouring which the ideal of British brotherhood, as realised at South Kensington, presented to the astonished gaze of the world at large, and we have followed with appropriate concern the unsuccessful efforts of those in authority to run the institute as a club or a tea garden. The poetry of the Imperial conception may be said to have finally disappeared when in 1900 the Government took possession and handed over to the University of London a large part of the actual buildings. In January last, through the agency of an Act passed in July, 1902, the institute was transferred to the care of the Board of Trade. With the assistance of an advisory committee, upon which are also represented India, the colonies, and the Board of Agriculture, Sir Alfred Bateman, K.C.M.G., now directs its fortunes, and, shorn of its former glories, the institute has sunk to the indignity of becoming a mere branch of the commercial, labour, and statistical department. As a result of these proceedings our patience has at last been rewarded, for there has just appeared the first "Bulletin of the Imperial Institute." Professor Wyndham R Dunstan, F.R.S., the director, was at one time at the head of the research laboratories of the Pharmaceutical Society of Great Britain and we are therefore not surprised to find that although commercial matters receive chief attention in the bulletin there is yet much of medical interest. Several drugs and allied materials have been subjected to examination by the scientific workers whom Professor Dunstan controls, with, it is claimed, results of permanent value. Thus *Podophyllum Emodi*, a plant common in Northern India, has been shown to be chemically very similar to the familiar *Podophyllum peltatum*. The therapeutical effects of the drug were studied by members of the St. Thomas's Hospital staff and they concluded that it constituted an efficient substitute for the latter species. It may be noticed in passing that these opinions are somewhat in conflict with the views of earlier investigators. An examination was also made of an Egyptian plant—*Hyoscyamus muticus*—and this also is said to have been proved to be of service, though in exactly what capacity is not clear. The chemical composition of certain oil-yielding nuts from Brazil, Portuguese East Africa, and British Honduras has been ascertained, while some useful information seems to have been gleaned as to the poisonous effects on horses and cattle of some Indian and Colonial fodder plants. There is also another field in which an attempt has been made to further medical progress. Office room has been provided for the Colonial Nursing Association—a body which selects trained hospital and private nurses for the Crown colonies and other British dependencies. There are, therefore, not wanting signs of vitality on the part of what is left of the institute and possibly in the future the scope of its operations may become as great as was hoped for when first the idea of its establishment took shape.

THE CENTRAL MIDWIVES BOARD.

Dr. J. Ward Cousins has kindly forwarded to us a copy of the minority report, signed by himself, by Dr. W. J. Sinclair, and by Mr. E. Parker Young, respecting the draft rules framed by the Central Midwives Board. As, however, the draft rules in question have not as yet obtained the approval of the Privy Council, as required by the Midwives Act, they are so far not available for comment and we consider that without them it is impossible to discuss the modifications proposed by the signatories of the minority report. When the rules have obtained the approval of the Privy Council we shall deal with the whole matter.

THE ANTI-SYPHILITIC TREATMENT OF TABES DORSALIS AND GENERAL PARALYSIS.

IN a contribution published in the *Philadelphia Medical Journal* of April 18th, dealing with the most recent developments in the treatment of tabes dorsalis and general paralysis of the insane—two diseases hitherto regarded as hopelessly incurable—Professor Leredde of Paris brings together a number of important facts and illustrative cases and indicates briefly the direction in which further development may be expected in this branch of therapeutics. Professor Renaut of Lyons had recently shown that the pathological changes in tabes dorsalis and general paralysis may be syphilitic without necessarily conforming to the old classical description of syphilitic lesions. Nageotte's recent observations have shown that tabes is a chronic inflammatory affection of the spinal meninges affecting with peculiar intensity the posterior spinal nerve roots. The appearance of the lesion is quite consistent with the syphilitic origin of tabes and the cerebro-spinal fluid shows a moderate or marked degree of leucocytosis. By "recovery" in tabes dorsalis Professor Leredde means the arrest of the destructive process, comparable to the arrest of pulmonary tuberculosis. Fournier, in a recent work on para-syphilitic affections (1899), quotes a case of tabes with arrest of symptoms for 16 years after having undergone anti-syphilitic treatment. Recent observations by Lemoine of Lille on the "intensive" mercurial treatment of general paralysis and of tabes dorsalis, an account of which appeared in an annotation in THE LANCET of Sept. 6th, 1902, p. 690, and additional observations made subsequently by Leduc, comprise ten cases of tabes dorsalis subjected to the "intensive" mercurial treatment, with the result that considerable sensory and motor improvement took place in all and some few were cured. As regards general paralysis Professor Leredde, after collating a number of cases, carefully observed and recorded by various authors—*viz.*, six cases by Lemoine, nine by Devay of Lyons, and three by Cassaet, and adding to these other cases under his personal observation, making a total of 26 cases—says that these 26 cases may be considered as showing that good prospects of recovery may be entertained for general paralysis—a disease hitherto universally regarded as hopelessly incurable and fatal. The following two typical cases may be cited as illustrative of the results of treatment for general paralysis. Case 1 was that of a male general paralytic with weakness of the lower limbs, vertigo and ataxia, disturbance of speech and of handwriting, loss of memory, and a grandiose mood. He was treated with three-fourths of a grain of calomel injected weekly into the subcutaneous tissue. After some months his speech and handwriting improved, his memory returned rapidly, and the mental state regained its normal character. At the date of publication of this case (by Dr. Devay in 1902) complete recovery had been maintained for some time. Case 2 was that of a male general paralytic with tremors of the lips and hands, irregularity of the pupils, dulness of memory, dementia with confusion of mind, and loss of control over the sphincters. Mercurial inunction was tried and found to be followed by improvement which was rapid at first and slower afterwards. Gradually the mental state returned to the normal level and the patient was able to return to his business. During the next five years further improvement was noted, recovery being considered as complete at the end of that period by Dr. Cassäet, under whose care the patient had been during all that time. Professor Leredde draws the following important and weighty conclusions. First, anti-syphilitic treatment in patients with tabes dorsalis or general paralysis should begin early. "Delay is dangerous, because while we wait irremedial degenerations of the nervous system may be occurring." Secondly, for vigorous adults from one-half to three quarters of a grain of mercuric benzoate in normal salt solution should be given hypodermically as the full dose, the first few injections being half a grain, slowly rising to three-quarters of a grain. Symptoms of intolerance, such as indigestion, loss of flesh, and febrile reaction, would indicate over-dosage, in which case the dose should be lowered. Thirdly, the daily dosage should be increased only very slowly and the mouth and gums should be kept clean. In this way, adds Professor Leredde, dangers are minimised and therapeutic accidents are avoided.

THUNDERSTORMS AND TELEPHONES.

It is well known, of course, that electrical disturbances in the air interrupt the telephonic and telegraphic services and it has been stated that powerful discharges have occurred at the terminals of public electrical apparatus during the passage of lightning overhead. A violent thunderstorm passed over the metropolis last Saturday and it is stated that during the whole time this electrical storm was in progress very alarming electric discharges took place over the two large telephone switch boards at the Southwark headquarters of the Metropolitan Fire Brigade over which news of calls from all parts of London is transmitted. It was reported that no apparent damage was done to the apparatus and it so happened that there were no messages calling for attention during the time the discharges induced by the storm were taking place amongst the instruments. There can be little doubt, however, that had the telephones been used some discomfort would have been experienced, not to say real injury sustained, by the person who may have employed the instruments at the time. Both telegraphic and telephonic services may become a source of danger during great electrical stress in the air and persons should be warned against using the instruments at such a time and certainly when alarming symptoms of a storm manifest themselves in the way just described. The incident suggests unpleasant possibilities in the case of electric wiring in the house, for in this way atmospheric electricity may possibly be an occasional factor in the origin of an outbreak of fire.

HAIR-BALLS IN THE STOMACH.

In the stomachs of many of the lower animals hair-balls are liable to form, and they are especially common in cattle. The hair is licked from the surface of the body, is carried into the stomach and is there subjected to a churning movement by which it is moulded together into a compact mass. This is greatly facilitated by the tendency to "felt" which is possessed in a high degree by the hair of cattle, so that these hair-balls are firm round bodies and show on section a lamination corresponding to the successive deposits of hair. In the human being hair is but rarely swallowed, though sundry cases are on record in which the practice has existed. In many of the persons in whom hair-swallowing occurs there has been a history of insanity, yet it has been seen in those who had no other sign of mental derangement. A large majority of the patients are women. Human hair has but little tendency to "felt," because its surface is comparatively smooth and therefore we practically never find in the human stomach hair-balls resembling those found in the lower animals. Generally in human beings the hair forms a somewhat loose mass conforming more or less to the shape of the stomach. The quantity of hair present may be very great. Mr. George May published a case in the *Medical Association Journal* of Dec. 28th, 1855, in which the mass of hair weighed 26 ounces. Mr. J. Knowsley Thornton[1] has recorded a case where the weight of the foreign body was two pounds. Dr. Russell published in the *Medical Times and Gazette*, vol. i., 1869, p. 681, a case in which the mass of hair weighed four pounds seven ounces, but larger still was the amount of hair in a case under the care of Mr. Paul Swain[2] for it weighed five pounds three ounces. It is not surprising that masses like these form very obvious swellings in the abdomen and we publish in the present issue of THE LANCET an account by Dr. H. Mallins of a case where the abdominal swelling was large and at the necropsy it was found to be due to a mass of hair in the stomach weighing one pound nine ounces. In a few instances the presence of a foreign body has been diagnosed and the mass has been successfully removed by a gastrotomy. This was done in Mr. Thornton's case and in Mr. Swain's case mentioned above. Schönborn[3] has also published a successful case, and a fourth is recorded by Berg of Stockholm. Unfortunately in most cases the accumulation of hair has only been discovered at the post-mortem examination.

THE MOTOR-CAR PROBLEM.

Sir Ralph Payne Gallwey in a recent letter to the *Times* makes a suggestion which we can hardly expect to see carried out but which nevertheless deserves serious consideration He says:—

> As a sure means of identifying the reckless "don't care-a-hang for anybody" motor-car drivers, the class of men who daily imperil our lives and who are responsible for the "motor murders" that too frequently occur, I would suggest a legalised use of the shot-gun. In the case of a motorist—by wilful neglect of ordinary precautions—inflicting injury on a pedestrian, or causing damage to the property of a person driving or riding on the highway, followed by an attempt to escape detection by continuing his rapid progress, I consider the injured party should be legally permitted to fire at the offender. The gun not to be used at a range exceeding 40 yards and the shot with which it is loaded not to be of a larger size than No. 8 or 9.

Sir Ralph Payne Gallwey goes on to say that the motorist would only be shot in the back and that he could easily be identified by the shot holes in his clothes when these were removed by the police of the town receiving an intimation by telegraph to detain him. Probably the offending motorist would avoid the next town, but although the point raised by Mr. W. S. Gilbert in his letter to the *Times* of June 3rd as to the ultimate career of the car must be remembered the idea is distinctly good and might be applied with advantage to many other nuisances, as, for instance, "winner" yellers, piano organists or preferably piano organs, advertisement vans and the idiot upon them who blows a horn, German bands, and the like. As we write a huge traction engine is going along the Strand dragging three enormous trucks loaded with blocks of wood for wood-paving. This sort of traffic should not be allowed in London and the driver of the engine is not responsible, so we fear that in this case the shot-gun would not do, but some of these days an aggrieved ratepayer will call on the contractor or on the borough council who employ him armed with a similar weapon.

---

[1] THE LANCET, Jan. 9th, 1886, p. 57.

[2] THE LANCET, June 22nd, 1895, p. 1581.

[3] Langenbeck's Archives, 1883, vol. xxix., p. 609.

The principle of the shot gun could be carried out just as effectually and without danger to life by casting a dose of indelible dye over the driver It would be a comparatively easy matter to supply the police with a rapidly acting dye squirt and the offender would certainly be marked and the marks unmistakeable If Sir Ralph Payne Gallwey's suggestion is worth anything at all it would be better and more humane to make the target not the driver but his air tyres That would effectually disable him, we fancy, without the drawback pointed out by Mr W S Gilbert Another method of pulling the motor car up in obedience to a signal would be to have a platform in the road provided with sharp points which could be made to present themselves when occasion demanded

THE PREVALENCE OF SMALL-POX

IN his report *for the four weeks ending* May 16th Mr F W Alexander, medical officer of health of the borough of Poplar, states that since his last report to the public health committee on April 24th nine more cases of small pox have occurred in the borough in connexion with a patient living in Ford road This patient was removed to the small pox hospital on April 20th and the other nine inmates of the house who had been exposed to the infection were taken to the council's shelter, Glaucus street Bromley, as mentioned in THE LANCET of May 16th, p 1392 They were vaccinated on April 21st, a date which was of course at least a fortnight too late for successful prophylaxis, and they were all removed from the shelter to the small pox hospital on various days from April 29th to May 18th. Four more cases have occurred since that time in a laundry in Poplar The recent history of the incidence of small pox in Poplar seems to show that there was an associated group in which one patient was the means of infecting 19 others The Local Government Board of Scotland intimates that during the period from May 16th to 31st inclusive six cases of small pox have been reported to it from the burgh of Dundee, one from *the burgh of Glasgow,* and *one from the burgh of Coupar* Angus

ACUTE GRAVES'S DISEASE WITH MANIA

IN the *Quarterly Medical Journal for Yorkshire and Adjoining Counties* for May Dr F R B Atkinson has described a remarkable case of acute Graves's disease with the rare complication of mania A man, aged 55 years, was seen on July 18th, 1902 He had felt ill for a month and he complained of languor, hoarseness, loss of flesh and palpitation He received a severe shock about 12 months before in consequence of loss of money and had never been himself since He was nervous and irritable and his speech was very rapid The thyroid gland, especially the right lobe, was much enlarged and pulsation of the carotids was visible There was no proptosis but his wife said that his eyes stood out at times There was marked pulsation over the whole cardiac area and in the epigastrium The heart was enlarged and there was a systolic thrill but no murmurs were heard The pulse was 108 small, and intermittent *Grafe's,* Stellwag's, and *Möbius's signs* were absent The patient rapidly became worse and on August 23rd diarrhœa and vomiting with tremors of the arms and legs, and sometimes of the jaw, set in Speech became much faster and at times was unintelligible On the 29th he cried and at night became maniacal, talking nonsense and shouting He could only be kept in bed with difficulty The right pupil was dilated The pulse was 130 and on the patient rising in the bed it became 140 Stellwag's sign was present On Sept 1st the *tache cérébrale* could be obtained and there was marked delirium On the 3rd the temperature was 101° F and there were dysphagia and râles at the bases of the lungs He was evidently dying On the 4th he was unconscious and his legs moved up and down continuously in a choreiform manner The goitre was much smaller and the pupils were equal Death occurred at noon Dr Atkinson thinks that the dilatation of the right pupil was probably due to irritation from pressure of the right lobe of the thyroid Its disappearance before death is explained by the diminution of the thyroid Mental disturbance in Graves's disease usually takes the form of melancholia Dr Atkinson has collected 25 cases in which mania occurred Of these 17 were fatal The disease in the present case was remarkably acute, its total duration appears to have been only two and a half months

"THE DIRTY FOUNTAINS IN TRAFALGAR-SQUARE"

WE *are glad to find that our remarks last week upon the* dirty condition of the water of the fountains in Trafalgar-square have raised considerable public comment on this matter We learn that the water which supplies the fountains is, as a matter of fact identical as regards its source with the water supplied to Buckingham Palace, Marlborough House, the Houses of Parliament and the Government offices The source is an artesian well and the water is pumped into tanks in Orange street, which are connected by a horizontal tunnel 400 feet in length which forms a reservoir with a capacity of 112 000 gallons. It would be interesting to determine the composition of the water supplied to the Royal residences and the Government offices in order to discover any essential differences which exist in relation to organic purity between the water of the fountain and this drinking supply Should analysis show—and we should not be surprised—a condition similar to that of the water derived *from Aldgate* pump *a few years ago* this source of supply would have to be discontinued We understand, however, that for the sake of economy the water pumped to the fountains is used over and over again If that is the case instead of being things of beauty and purity the fountains are circulating and disseminating filth in the manner indicated by the analysis which we published last week. Apart from fountains Trafalgar square is a disgrace This "finest site in Europe is little better than a refuse catchment area patronised chiefly by ragged urchins and dirty people We are glad to see the suggestion that the asphalte area should be converted into "a glowing parterre of colour" by removing the asphalte altogether and replacing it with grass and flowers

QUACKS IN GERMANY

IN the *Standard* of June 1st appears the following message *from* the *special correspondent of that journal* at Berlin dated May 31st —

> The Imperial Home Office has addressed a circular to the Federal Governments on the subject of quack medicines and doctors It proposes that stringent measures shall be taken against what is described as a growing evil which it is said has assumed proportions in Germany which are decidedly dangerous to the public welfare Amongst the measures proposed is one for the compilation of a register in which all the names of all quack doctors have to be entered It is also proposed that obvious exaggerations in newspaper advertisements by quacks shall be prohibited The police it is suggested should be authorised to prevent quacks *from exercising their calling whenever there is reason to believe that a continuation of their practice would* be injurious

We wonder when our Imperial Government will take a similar step A press censorship does not exist in these islands and to the credit of British journalism such a censorship as regards the body of a journal is not needed But when we look at the advertisement columns the case is different Journals of the highest standing insert page advertisements of such well known quackery as the Drouet Institute, while the advertisement columns of the popular monthly magazines are crammed with notifications of all sorts of quack remedies including those emanating from the scoundrels who trade on the fears of sexual hypochondriacs. The flagrant advertisements from abortionists seem to have received a check owing, we think we may say, in great part at least, to the articles which appeared in our own columns on the matter, but "Dr." Bell and others of his kidney still advertise their deceptions in newspapers and magazines and distribute lures for dupes broadcast with the connivance of His Majesty's Postmaster-General. Such things should not be and the sooner that our Government takes up the matter the better.

THE WORTHLESSNESS OF ABSENCE OF LIVER DULNESS AS A SIGN OF PERFORATION OF THE STOMACH OR INTESTINE.

IN THE LANCET of April 18th, p. 719, we published an annotation in which we drew attention to the uselessness of the absence of liver dulness as a sign of free gas in the peritoneum, though many still attach some value to this physical sign. Dr. Charles Viannay of Lyons has brought to our notice a paper which he read when he exhibited a specimen of very great interest at the Société des Sciences Médicales de Lyon on Dec. 17th, 1902, and which was published in the *Lyon Médical* of Feb. 8th, 1903. Dr. Viannay is prosector to the Faculty of Medicine of Lyons and in the dissecting room he found a liver which showed on the upper surface of its left lobe a well-marked impression due to the transverse colon, a loop of which had insinuated itself between the upper surface of the liver and the diaphragm. The body was that of a woman, about 40 years of age, who had died from an extensive cellulitis of the neck The liver weighed 1320 grammes (42½ ounces) and bore evident traces of constriction from the corset, for the upper surface of the right lobe showed four long and deep costal impressions. The gall-bladder was hidden under the ribs near the hepatic flexure of the colon, to which it was attached by old adhesions. The right half of the transverse colon was adherent to the anterior edge of the liver, under which it was lying as far as the falciform ligament. Immediately to the left of this ligament the colon turned round the anterior border of the liver and formed a large loop which passed later over the front of the stomach to the splenic flexure. This condition is rare, but Dr. Viannay has discovered other instances of it. Mauclair and Mouchet[1] described a case where the transverse colon formed a loop between the right lobe of the liver and the diaphragm, passing as far back as the coronary ligament. Cohan[2] saw four cases in which a similar condition obtained. Other instances have also been recorded It is obvious that such an interposition of bowel between the liver and the abdominal wall would cause absence of more or less of the liver dulness according to the amount of bowel involved, and therefore absence of the hepatic dulness can have no value as an indication of perforation. In the discussion which followed the reading of the paper which we have mentioned Dr. Mouisset remarked that the liver dulness may be absent for several reasons and Dr. Jaboulay said that he had seen the liver dulness absent in cases of gaseous cysts of the intestine.

THE Harveian Lectures of the Harveian Society of London will be delivered by Dr. D. B. Lees on Nov. 5th, 12th, and 19th of this year at the Stafford Rooms, Tichborne-street, Edgware-road. The subject of the lectures will be the Treatment of some Acute Visceral Inflammations.

WE regret to announce the death of Mr. Alfred Haviland, M R C.S. Eng. Mr. Haviland, who passed away on June 1st at the age of 78 years, will be remembered as having done much excellent work on the subjects of medical geography and climatology as concerned with the distribution of disease.

THE annual dinner of the Indian Medical Service will b held at the Café Monico. Piccadilly-circus, on Thursday June 11th, at 7.45 P.M., when the chair will be occupied b Surgeon-General Sir Annesley De Renzy, K.C.B. Officer intending to be present should communicate at once wit the honorary secretary, Mr. P. J. Freyer, 46, Harley-stree W.

Dr. J. J. R. Macleod assistant demonstrator of physiolog at the London Hospital, has been appointed Professor Physiology at the Western Reserve University, Clevelan Ohio, which celebrated its sixtieth anniversary this yea Dr. Macleod graduated in 1898 with honours at the Universit of Aberdeen.

Dr. W. Collingridge, medical officer of health of t City of London, will preside at the eleventh ann meeting of the Church Sanitary Association at the Chur House, Westminster, S.W., on Wednesday, June 24th.

THE annual dinner of the Royal Army Medical Cor Militia will be held on June 8th at the Trocadéro Restauran Piccadilly Circus, London, W., at 8 P.M. Medals and orde will be worn.

THE CORONERS' SOCIETY OF ENGLAN AND WALES.

ANNUAL MEETING.

THE annual meeting of the Coroners' Society of Englar and Wales was held in the Holborn Restaurant on May 28t Mr. H. J. ROBINSON (Blackburn and Burnley), the retirin President, was in the chair and about 50 gentlemen we present.

The minutes of the last annual meeting having be adopted the election of officers for the forthcoming sessi was proceeded with. Mr. J. BRADLEY (Birminghar proposed Mr. Henry White (Hants and Winchester), t senior vice-president, for election to the office of presider remarking that the gentleman was a very old member their council and most diligent in his attendance. M SPENCER CLARKE (Hants) seconded the motion which w carried unanimously.

Mr. WHITE then took the chair and in thanking t proposer and seconder said that the experience of the latt as a coroner went back for 40 years, while he himself (M White) had now been a coroner for nearly 30 years.

A vote of thanks to Mr. Robinson, the retiring pr sident, was proposed by the new PRESIDENT, seconded Mr. G. E. ROUMIEU (Surrey), and carried unanimously. On the motion of Mr. ROBINSON, seconded by Mr CHRISTOPHERS (Warwickshire), Mr. S. F. Butcher (Bur was re-elected as a vice-president and Mr. G. Percev Wyatt (London and Surrey) was chosen to succeed M White as a vice-president.

The PRESIDENT, in proposing the re-election of M Walter Schröder (deputy coroner for London Centr District) as honorary secretary, said that everyone kne something of the work which Mr. Schröder had done in th capacity. It was to all of them a source of extreme gratific tion when Mr. Schröder expressed his willingness once mo to undertake the duties of the office.

Mr. BUTCHER indorsed all that had been said by t President in Mr. Schröder's praise and at the same tir seconded the motion which was carried unanimously.

Mr. SCHRODER, after thanking the meeting for his electio remarked that the report which he had prepared was som what lengthy on account of the number of subjects whi had to be dealt with. By way of appendix to the report h had been able, through the courtesy of Messrs. Benholm the proprietors of a local newspaper at Colchester, reproduce an illustration of treasure-trove found in th ancient city. The report contained another illustratio reproduced from the *Sphere* by the courtesy of the Nineteen Hundred Publishing Syndicate, Limited, who lent the engraved block, and by permission of the family of the late Mr. Wakley. This was a copy of an old print of an inquest held by Mr. Thomas Wakley, M.P., by whose side, on the left, stood Charles Dickens. Mr. Schröder was of opinion that the inquest there depicted was held in central London, probably in St. Pancras, and that the sketch was by George Cruikshank, whom he knew. On several occasions that artist attended inquests held by the late Dr. Lankester and Dr. Hardwicke and it was quite possible that he was present at some held by Mr. Wakley.

---

[1] Bulletin de la Société Anatomique, 1896, p. 600.

[2] Recherches sur la Situation du Colon Transverse. Thèses, Paris, 1897-1898, tome 11.

Mr. Perceval Wyatt was then re-elected honorary treasurer and some vacancies on the council were filled.

Mr. SCHRODER, the honorary secretary, moved the following addendum to Rule 1 of the society :—

> And that coroners and deputy coroners outside England and Wales be admissible as extraordinary or corresponding members.

The need of this addition to their rules was, he said, to enable coroners in other parts of the empire and elsewhere to join the society as corresponding members; any coroner in Ireland, for instance, who might wish to join them could do so in this way. The motion was seconded by the coroner of Rochester and carried unanimously.

The meeting then proceeded to consider the council's report.

On the motion of Dr. AMBROSE, seconded by Mr. J. BELL, the subjoined motion was carried :—

> That this annual meeting of the Coroners' Society desires to call attention to the present unsatisfactory state of the law dealing with the provision of places for the holding of inquests and the performing of post mortem examinations and requests the council to approach the Home Secretary on the matter.

The meeting closed with votes of thanks to the honorary secretary and the honorary treasurer for their services during the past year.

ANNUAL BANQUET.

The annual banquet of the society took place on the same evening. The President was in the chair and a large number of coroners and guests were present.

After the loyal toasts had been duly honoured Mr. BUTCHER gave "The Houses of Parliament," the toast being acknowledged for the House of Lords by Lord MONKSWELL, chairman of the London County Council, in a humorous speech. Mr. LUKE WHITE, who responded for the House of Commons and is himself a coroner, dwelt upon the part played by coroners in the securing of domestic legislation and in promoting the interests of the poorer classes.

"The Imperial Forces" was proposed by Mr. I BRADLEY, coroner for Birmingham, who remarked upon the voluntary character of the services rendered by the Imperial forces and paid a special tribute to the work and character of the police. This toast was responded to by Major READ

Mr. MACMORRAN, K.C., in proposing "The Coroners' Society," observed that the society was established in 1846 to protect and to further the interests of coroners. But since then its scope had been very much enlarged and not only had it been the means of helping to raise the status of the coroner largely in public esteem but it had done good work in the interests of the people and was now a real power in this kingdom, its advice being often sought and the voice of the society having weight in influencing legislation in many ways. He also remarked that, at all events in London, inquests were rarely held as of old in public-houses, but that coroners' courts, mortuaries, and post-mortem rooms had been provided by the county council and local authorities which had long been suggested and urged by the society. He gave "The Coroners' Society, long may it prosper."

The PRESIDENT, in replying, said that in no other case did more depend upon the man and less upon the office than in that of a coroner; for a coroner had to exercise much tact and to show great judgment in discharge of the various difficult duties which fell to his lot. He referred to their relations with the poorer classes of His Majesty's subjects, to the services that coroners were able to render in assisting in bringing about legislation of benefit to them, and to the many cases of sorrow and sadness which came before them and in some of which they were able to give balm and comfort in times of deep distress. In concluding he remarked that he thought that inquests held in public-houses would soon be a thing of the past.

The health of the retiring President, Mr. Robinson, was then proposed and suitably acknowledged.

The toast of "Our Guests" was given from the chair in cordial terms and briefly responded to by Sir A. de RUTZEN.

"The Officers of the Society" coupled with the name of the honorary secretary, was the last toast, in proposing which the PRESIDENT referred to the pleasure it gave the members that Mr. Perceval Wyatt should retain the treasurership in addition to the vice-presidency to which he had that day been elected. The services which Mr. Schröder had rendered to the society were much appreciated, and it was a matter of great gratification to him personally and to the members generally that Mr. Schröder had consented to continue as their secretary.

Mr. SCHRÖDER, in replying, said that it was with some diffidence that last year he took office, as he had little spare time at his disposal, and especially as he had not the advantage of being either a medical or a legal man, to say nothing of the combination of both law and physic possessed by many coroners in the present day. However, favouring circumstances of many years of coroner's work had enabled him to gain a somewhat extensive experience of the law and practice of the coroner's court which had served him in good stead and he was glad to find had proved useful to others. He had long recognised that reforms in the coroner's court might be made with beneficial effect to meet the changing condition of the times and to insure greater uniformity in practice and with advantage to the public interests His desire was to help forward any such movement and in using his endeavours to that end he felt sure that he would thereby assist in maintaining the dignity and honour of the office of coroner. He would always be pleased to do all he could for the benefit of the society.

The pleasure of the evening was enhanced by some excellent vocal music.

ARMY MEDICAL DEPARTMENT REPORT FOR 1901.

THE Army Medical Report for 1901 has just been issued. In addition to the usual statistical returns and statements regarding the health and sanitary condition of the troops serving at the various stations and commands at home and abroad it contains a report on the Progress of Hygiene for the year 1901–02, by Major R. H. Firth, R.A.M.C., professor of military hygiene in the Medical Staff College, London; a list of Operations with Notes on the more [illegible] and Remarks on the Work in the [illegible] Royal Victoria Hospital, Netley, [illegible] Colonel W. F. Stevenson, C.B., R.A.M.C., the professor, and Lieutenant-Colonel W. Dick, R.A.M.C., assistant professor, of military surgery at the Army Medical School; and a Report on the Medical History of the China Campaign of 1900–01.

To begin with the excellent prefatory summary statement as to the health of the troops at home and abroad we may usefully refer to some of the more salient points presented.

The average strength of the European troops, exclusive of those in South Africa, in 1901 was 196,796 warrant officers, non-commissioned officers, and men. The total number of admissions to hospital was 172,908 and the total deaths were 1762. The admissions represent a ratio of 878 6 per 1000 of strength; the deaths one of 7·70 per 1000 on a strength of 228,816, which includes detached men not shown in the returns received.

As regards the troops serving in the United Kingdom there is nothing which strikes us as calling for special remark. The admission and constantly sick rates were higher and the mortality rate was lower than in 1900. There were 157 admissions to hospitals and 39 deaths from enteric fever. An outbreak of that fever at Portland was supposed to be due to the mingling of returned South African convalescents with young soldiers in their barrack rooms, conditions which it need scarcely be said were soon remedied.

At Gibraltar the health of the troops was favourable as compared with 1900. There were less enteric fever and a marked decline in the admission rate for venereal disease In the Malta command, which included Crete, the admission, mortality, and constantly sick rates were slightly higher than in the previous year. Ague was very prevalent in Crete in 1901—indeed, the disease was epidemic there during the latter portion of that year. It is pertinently remarked that in the native town of Kandia, which is close to the camp, mosquitoes of the anopheles and culex species abound and there is also a large marsh not many miles off. The health of the troops in Canada was good on the whole. In Bermuda the decline in enteric fever previously reported was maintained in 1901. We notice that five admissions and four deaths from yellow fever at St. Lucia are recorded, attributable, it is alleged, to the probable importation of the disease into the colony by shipping from South America. As regards South Africa it has to be borne in mind that no annual returns of sick have been submitted and that consequently no statistics for comparative purposes can for the present be prepared. The health of the troops in Mauritius was on the whole good. There was an increase in the prevalence of malarial fevers as compared with 1900. The troops had escaped plague which was prevalent throughout the island. In Ceylon it is mentioned that there were a large number of cases of enteric fever among the Boer prisoners of war at Diyatalawa camp and that three cases of enteric fever occurred among the men of the military guard at that camp. The health of the troops in the Straits Settlements is stated to have been most satisfactory. Two admissions from plague, both of the cases being fatal, occurred among the troops serving in China, where the disease, it will be remembered, was epidemic among the civil population in 1901.

In India there was a decrease in the admission, mortality, and constantly sick rates, but an increase in that of invaliding. The chief causes of sickness, as usual, were malarial fevers and venereal diseases, which together caused 52 11 per cent. of the admissions for all diseases. As regards enteric fever, it is noted that not since 1887 has there been a lower admission rate, while the death-rate is less than in any year since 1884. The cessation of the usual reliefs and the retention of time-expired men in the country are cited as agents in bringing about the reduction, but credit would also appear to be due to the greater care taken with regard to soldiers' food, drink, and sanitary surroundings, and to the absence of field service, although it still remains to be seen what effect the arrival of large drafts of young soldiers will have on the prevalence of the disease. During the year only 12 fatal cases of cholera occurred and there were also two admissions for plague, one case resulting fatally.

In Egypt the admission, death, and constantly sick ratios were higher than in 1900. Influenza caused 361 admissions, all the cases occurring at Cairo, where the disease assumed an epidemic form in July, August, and September. The ratio of admission for enteric fever was practically the same as in the previous year.

THE MEDICAL DEFENCE UNION.

ANNUAL GENERAL MEETING.

THE annual general meeting of the Medical Defence Union was held on May 21st at 4, Trafalgar-square, London, Mr. M. A. MESSITER, the PRESIDENT, being in the chair.

The report of the council, to which we refer more fully below, contained a satisfactory account of the successful progress of the union.

The PRESIDENT, in moving the adoption of the report of the council, said that the union was full of vigour and reviewed the work carried through in 1902, describing it as excessive, varied, and important. Questions dealing with unqualified practice, medical aid societies, advertising, covering, libel, slander, malpraxis, boards of guardians, hospital boards, and infectious diseases had been fought out on the principle of never compromising in any case and in every one the union had been successful.

Dr. W. S. A. GRIFFITH seconded the motion and said that in his opinion if the entrance fee was made one guinea instead of 10*s*. the council would be doing a right and proper thing.

After some discussion the report was adopted unanimously.

The adoption of the accounts for 1902 was proposed by Dr. HEDLEY HILL, seconded by Dr. J. T. MACNAMARA, and carried unanimously.

On the motion of Dr. H. CAMPBELL POPE, seconded by Dr. W. RIGDEN, provision was made for the payment of railway fares to the members of the council attending meetings from the provinces.

The meeting terminated with a vote of thanks to the executive after the re-election of the following members of council: Dr. M. Beverley, Mr. T. Garrett Horder, and Dr. W. Rigden.

ANNUAL REPORT.

We have received a copy of the annual report and statement of accounts for the year 1902 of the Medical Defence Union. The objects of the union are too well known to need detailed repetition here and the council and members may be congratulated on the continued and satisfactory progress of the society. During the past year 896 new members were elected, a number which in itself is sufficient proof that the efforts exerted by the managing council have received due approbation at the hands of the profession in general; for not only does the society concern itself with the affairs of its members but also undertakes the prosecution of unqualified persons when such cases are brought under its notice and also conducts cases before the General Medical Council when alleged grave unprofessional conduct is imputed. The services thus rendered to the whole of the medical profession are very great and deserve the recognition which has been accorded during the past year in the shape of the greatly increased entry of new members. In the report before us several cases are recorded in which the union has been of public service. Especially noteworthy is the prosecution of a man who passed under the names of Dr. Hoffmeister, Dr. Dobie, and Dr. Elliott, and who was charged with manslaughter and perjury. It was entirely due to the efforts of the union that he was finally traced, arrested, and sentenced to five years' penal servitude. During the trial a very important ruling was propounded by Mr Justice Bigham. He pointed out to the jury that the prisoner went under three false names, all of which were upon the Medical Register, but none of these was his own name. This fact was not in itself evidence of negligence, but if a man like the prisoner did hold himself out to have medical skill he gave it as his opinion that the act constituted in itself gross negligence and directed the jury to take this as his ruling on that point.

Another striking point in the report is the varied nature of the claims for advice and assistance which are dealt with by the general secretary (Dr. A. G. Bateman). Information was sought on the Acts of Parliament dealing with lunacy, inquests, the Poor-law, vaccination, public health, employers' liability, notification of disease, vivisection, the law of partnership, coroners, and other points requiring legal assistance. When advice of this nature is sought the matter is promptly dealt with, Dr. Bateman or the solicitor to the union, Mr. W. E. Hempson, at once taking action if the case is so urgent as not to be capable of postponement until the next meeting of the council or of the executive committee.

The influence of the union is making itself very generally felt, not only amongst its own members for their own benefit but also in other ways, as explained by Mr. Hempson in his report. The chief items of expenditure were incurred in cases in which, although the union has proved successful, it has been unable to recover any portion of the costs owing to the pecuniary position of the litigant. The man who has nothing to lose has everything to gain and if he can find a solicitor who is prepared to conduct a case on the chance of securing either a favourable compromise or a verdict in his client's favour then the litigant is well content. But solicitors of this class are now extremely wary of carrying an action to any great length when they find that the medical man concerned is a member of a society for medical defence. In many cases it is quite sufficient for the secretary of the society to write and to inform those solicitors that the case has been placed in the hands of the society for the action to be at once abandoned.

At the present time the membership of the union is approximately 6000. An enormous number of cases were dealt with during the year, as a glance at the schedule of cases selected from the minute-book will show. 155 cases were referred to the solicitor, all of which necessitated either legal action being taken on behalf of the members concerned or legal advice and assistance being accorded to them. One important change in the management of the union during the past year was effected by an entrance fee of 10*s*. being imposed upon all new members. Although the funds of the union are in a perfectly stable condition yet the number of cases which require aid and advice has increased rather than diminished and the necessary cost of taking action before the legal tribunals makes a heavy inroad into such funds. It is true that, owing to careful management, the union has had for many years (and has at the present time) a balance in hand at the termination of each financial year, but at the same time it was felt very strongly that this margin of income over expenditure was not sufficient to relieve the council from some measure of anxiety at the close of each year when heavy legal costs have to be met. After prolonged and careful consideration, therefore, the council decided to adopt the imposition of an entrance fee. We have no doubt that the decision was a right and just one. Increase of membership means increase of responsibility and the sum of 10*s.* will, we feel assured, have no deterrent effect in preventing the entrance of new members. Medical men, no matter which branch of the profession they take up, are constantly liable to be attacked by impecunious and malicious individuals for the purpose of levying blackmail. It is therefore of the greatest comfort to a practitioner to feel that he has support behind him upon which he can rely to assist him with the best legal advice without the ruinous costs which may ensue if he has to meet the charge entirely on his own behalf. We heartily wish the union and other similar societies continued success.

MEDICINE AND THE LAW.

A Case under the Dentists Act.

AN unqualified person practising dentistry was recently summoned under the Dentists Act (41 & 42 Vict. C. 33, Sec. 3) for unlawfully taking and using an addition or description, "R.D.S. Eng., Surgeon Dentist," implying that he was registered under the Dentists Act, 1878. The magistrate dismissed the summons and the Divisional Court has now upheld his decision on the ground that it was one of fact and consequently not one with which the court could interfere, its duty being to hear appeals upon questions of law only. The facts alleged are peculiar and the result may be somewhat serious if unqualified practitioners of all kinds take to following the example set them in this case, unless it can be shown that in such circumstances some other offence than that of taking a title implying qualification is committed. The defendant in the case under consideration bought the practice of a properly qualified dentist who had died, took over the premises in which the deceased had practised, and put up on the front railings his own name upon a marble slab, thus: "Mr. W. Lawson Whitlock, 10-5." He also left up the name of his qualified predecessor in all the places in which that gentleman had put it, with the result that "Mr. R. O. Stent, R.D.S. Eng., Surgeon Dentist," appeared in two places on or about the house and in another "Messrs. Stent, Surgeon Dentists. Est. 1840. Hours of attendance 10 to 6 or by appointment." To a patient he appears to have said in answer to a question as to whether he was Mr. Stent, "Mr. Stent is dead: I am Mr. Whitlock." These were the facts alleged as evidence that the defendant had "taken and used" titles implying that he was possessed of qualifications to practise dentistry. It is clear that a natural result of what was done would be to cause persons going to the house to think that the person operating on them was qualified, but that was not the offence charged. Upon the question of the taking and using the Lord Chief Justice intimated that he himself might have come to a different conclusion from that of the magistrate had he occupied his place, but that did not entitle him to say that there must be a conviction. [illegible]

to be one [illegible]

as there i[illegible]

Divisiona[illegible]

the case commented on was not one of the ordinary instances of taking and using a description implying qualification; it was probably not a case contemplated by those who framed the Act and consequently the language used was not sufficient to meet it. At all events if any unqualified person adopts the same course as Mr. Whitlock in the future he will do so with impunity, unless either the magistrate before whom he is brought takes a different view from that of the gentleman before whom Mr. Whitlock appeared or a different charge, based possibly upon the inducing patients to believe him to be qualified, can be sustained. If no penalty can be enforced for such conduct the prospect is somewhat serious. The practice of a deceased qualified medical practitioner or dentist may be worth very little to the executors, but the right, if right it can be called, to put his own name-plate under one which records recognised qualifications may be worth a great deal to a quack. Moreover, it is not absolutely clear that the right need be acquired in the sense in which Mr. Whitlock acquired it or that there need be any show of right at all. If Mr. Whitlock had put up a wholly fictitious name with wholly fictitious qualifications he would not apparently have been held by the magistrate to have been taking and using an addition or description within the Act, for the magistrate evidently thought that the addition or description must be appended to the name of the user of it in order to constitute the offence. A person so using a fictitious name might be convicted if charged with obtaining money by falsely pretending that he was a qualified person, but prosecutions of this kind are not always easy to bring to a successful conclusion and it is a matter to be regretted by the public and by the medical profession that the Medical Acts should not afford them the certainty of protection upon such occasions.

The Registration of Children

The lady, named Bedford, who was convicted and fined £10 by Sir Albert de Rutzen for giving false information to a registrar of births concerning the birth of a child, was perhaps fortunate in that prompt discovery followed her action. Apparently she was desirous of adopting a child. What the motive may have been we need not inquire or discuss, but she obtained a female child from a young single woman who had recently been delivered, and not content with taking the infant and treating her as her own she caused her to be registered as having been born at an address in Upper Woburn-place, and gave her own name and that of her husband as the names of the parents. In Mrs. Bedford's case the unexpected appearance of a child apparently provoked immediate surprise and comment. In some families where the members are scattered and live without communicating with one another, such deceit practised upon a registrar might easily pave the way to serious confusion and error in the future. Apart, however, from the possible perpetration of fraud, the registers of births, marriages, and deaths play so important a part in the organisation of the protection of the public health and safety and are so difficult to maintain with the desired accuracy that any attempt deliberately to falsify them deserves very severe punishment indeed.

An Undesirable Midwife.

At Dewsbury a midwife who failed to put in an appearance at an adjourned inquest was recently ordered by the coroner to be arrested and imprisoned for 24 hours. At the opening of the inquest on a previous day she had arrived under the influence of drink and had been severely censured by the coroner. A medical man who had made a post-mortem examination of the infant's body which formed the subject of the inquiry stated that death was due to insufficient inflation of the lungs and the jury found a verdict of "Death from natural causes aggravated by want of attention at birth." The medical witness stated with regard to the midwife that it was six years since he had attended a confinement at which she had been engaged and that he had then warned her not to go near any case with which he might be connected on account of her filthy and drunken habits. She had been fined for being present at a confinement after attending an infectious case. The Midwives Act will, doubtless, in time provide protection for the poor against such persons as this. The name of "Mrs. Hardy" is not likely to appear upon the roll of midwives as having practised as a midwife and borne a good character so as to enable her to be registered before April, 1905.

THE CENTRAL MIDWIVES BOARD.

A MEETING of the Central Midwives Board was held on May 28th at the Privy Council Office, Whitehall, when the following business was transacted: 1. A letter was read from the secretary of the Liverpool Ladies' Charity and Lying-in Hospital praying for the recognition of its certificate in midwifery as a sufficient qualification under

Section 2 of the Midwives Act, 1902. The secretary was instructed to reply that the application would have the careful consideration of the Board when it came to deal with the question of the acceptance of "other" certificates under Section 2. 2. A draft form of notice of the effect of the Act for the use of local supervising authorities was considered, amended, and approved. 3. The secretary reported as to negotiations for acquiring suitable offices for the Board and further instructions were given to the sub-committee in charge of the matter. 4. The secretary was instructed to prepare for the consideration of the Board at its next meeting draft forms of (*a*) Midwives Roll and (*b*) certificate under the Act.

THE MEDICAL, SURGICAL, AND HYGIENIC EXHIBITION.

THIS annual exhibition was opened at Queen's Hall, Langham-place, on June 2nd and the continued interest shown alike by exhibitors and visitors in the proceedings affords evidence of the success of the scheme which was instituted seven years ago. Undoubtedly members of the medical profession find a visit, however short, to this exhibition instructive, judging from the numbers known to attend and the organisers may be congratulated on the practical encouragement that they have received in past years. The movement which they initiated has now become a regular institution which is appreciated by medical men, pharmacists, public health officers, and others.

It can hardly be expected that each year the exhibition can be exclusively devoted to absolute novelties, nevertheless a number of novelties will as a rule be found to attract the attention of the visitor. This year special foods and food products undoubtedly predominated over drugs and surgical appliances, although sanitary appliances seem to occupy a larger share of the space than on former occasions. By far the majority of the food preparations shown have already received attention in THE LANCET Laboratory, the results of their analysis having been presented to our readers from time to time. We may mention, for instance, the food preparations of the Shredded Wheat Co. (6 and 8, Eastcheap, London, E C.), including the shredded whole wheat biscuit which contains the entire constituents of wheat and the solubility of which has been increased by the special process adopted during its manufacture. A recent introduction of this company is the "triscuit" which is a wafer formed of shredded wheat containing the constituents of the wheat intact in a palatable form and shape. Quite recently we recorded the results of analysis of some of the Telma foods (Telma, Limited, 57, Fenchurch-street, London E.C.), which consist generally of malted cereals of an easily digestible character and also of high nutritive value. One of the first preparations to contain the casein of milk was "protene," upon which we reported some years ago. This product is added to bread, biscuits, chocolate, and cocoa, with obvious dietetic advantage. We have also recorded our laboratory experience of the dietetic value of peptenzyme (Carnrick) of the Peptenzyme Company (80, Gloucester-road, South Kensington, London, S.W.). We were able to confirm the activity of this preparation by which it is able materially to help the processes of nutrition. The maltine preparations of the Maltine Manufacturing Co. (25, Hart-street, Bloomsbury, London), are also well known and it is evident that these preparations maintain their standard position amongst food adjuncts. We expressed our opinion a short time ago on the preparation then called primox but now known as vegox, supplied by Primox, Limited (53, New Broad-street, London, E.C.), which is made from both meat and vegetables. The preparation is decidedly more palatable than simple meat extract, while its nutritive value is certainly not less. Karnoid, Limited (6 and 7, Stonecutter-street, Ludgate-circus, London, E C.) exhibited the recently improved form of karnoid. It is a fact of no small importance and much in favour of this preparation that it is prepared without resource to chemicals or preservatives and yet contains the nourishing constituents of meat unaltered, amongst which, of course, is the myosin albumin. Messrs. G. van Abbot and Sons (Baden-place, Crosby-row, Borough, London, S.E.) showed a useful assortment of foods suitable for the use of diabetic patients, dyspeptics, and invalids. Maggi's consommé, tonic bouillon, soups, and essences are well known not only for their excellent flavour but also for their nutritive value, as shown by some analyses which we have made. These preparations were exhibited by Messrs. Cosenza and Co. (95, Wigmore-street, Cavendish-square, London, W.). A novel preparation is "maltova" (Maltova, Limited, Leeds and London), a combination of active malt extract with raw eggs. The genuineness of the preparation, as we have already pointed out, is shown by (1) that it readily converts starch emulsion into soluble starch and finally maltose; (2) that it turns nearly solid on heating, this being due to the coagulation of egg albumin; and (3) that it contains phosphorus and sulphur in organic association. A similar preparation, in which the egg is first dried by a special method and its nutritive constituents thus concentrated, is the condensed egg syrup of the Condensed Egg Syndicate (85, Tooley-street, London, S.E.). Preparations are made containing either the yelk or white of egg or both. Again, dried eggs themselves without any addition are prepared and there is also a combination of the nutritive elements of fresh eggs with active malt extract which is known as "ovo-malt." Messrs. Callard and Co. (65, Regent-street, London, W.) exhibited several new foods adapted for patients suffering from diabetes or obesity. In addition to special breads and biscuits they prepare also sugarless marmalade, chocolate, and jellies. The patent groats and barley of Messrs Keen, Robinson, and Co. (Garlick-hill, London, E.C.) have been before the medical profession for a great number of years as a well-known source of food for infants and invalids when used in the form of barley-water. The British Somatose Co. (165, Queen Victoria-street, London, E C.) exhibited their somatose preparations, the basis of which is albumose. Clinical trial has shown somatose to be a true meat nutrient. A great assortment of meat preparations were exhibited by the Liebig's Extract of Meat Co., Limited (4, Lloyd's-avenue, London, E.C.), and a similar series of preparations was shown by Bovril, Limited (152 to 166, Old-street, City-road, London, E.C.). Malted foods were well represented in the exhibit of the Hovis Bread Flour Co. (Macclesfield), a feature of the exhibit being the Hovis food for infants and invalids, upon which we have analytically reported in our columns. Quite recently also we have referred to Moseley's food (Moseley's, Limited, Stockport) which is essentially a cereal food rendered more soluble and digestible by a special method of treatment. Cerebos salt (Cerebos, Limited, Newcastle-on-Tyne) marks a distinct advance on the old table salt; it is beautifully fine and white and, owing to the addition of phosphates, does not cake or become wet Plasmon is now universally known to the profession and is recognised as a powerful food which is rapidly assimilated and therefore of particular value in wasting diseases. Specimens were shown of the pure proteid and of its combination with beef, cocoa, and arrowroot by International Plasmon, Limited (56, Duke-street, Grosvenor-square, London, W.). To many persons "Hipi" recommends itself, being an extract of mutton of decidedly nutritive value, while it is palatable to the taste. Lozenges containing mutton extract, suitable for use when ordinary food cannot be obtained, were also a feature of this exhibit (G. Nelson, Dale, and Co., 14, Dowgate-hill, London, E.C).

As we have already stated, the display of drugs was on a decidedly smaller scale than in previous years, although there were some new preparations well worth bringing to the notice of the medical profession. Amongst these should be mentioned "antiphlogistine" of the Denver Chemical Manufacturing Co. (110, Cheapside, London, E.C.). Antiphlogistine is an advance on the old-fashioned cataplasm and consists of a uniform paste with an agreeable smell due to well-known antiseptics. The basis is a pure silicate. Spread over the tissues antiphlogistine keeps them agreeably moist and has a decidedly sedative effect Ovolecithine is the pure distearo-glycerophosphate of choline prepared from the yelk of egg which has been used with advantage in those neuroses which indicate exhaustion of the nervous system. This interesting phosphorous substance may be had in the form of pills, confection, or injection which are supplied by Billon's Ovolecithine Co. (16, Water-lane, Great Tower-street, London, E.C.). Messrs Bengué and Co. (Paris and 35, Alfred-place, London, W.C.) exhibited specimens of "narcotile," the bichloride of methylethylene, together with an apparatus for its administration. On the same stall specimens of "anæstile," a mixture of ethyl and methyl chloride, were shown and also a number of appliances for administering anæsthetics Mr. W. Martindale (10, New Cavendish-street, London, W.), had a profuse assortment of medical apparatus, besides a number of pharmaceutical preparations Messrs. Cooper and Co. (80, Gloucester-road, South Kensington) included in their tastefully arranged exhibit their oxy-carbonated mineral waters and a number of beef preparations distinguished by the term "globena" The exhibit also included some special pharmaceutical preparations The Salt Union Limited, through their agents Weston and Westall, Limited (41, Eastcheap, London, E C), exhibited samples of Droitwich brine crystals which are specially well adapted for the preparation of brine baths They also showed specimens of a new table salt known as "star salt" which is so prepared that it does not absorb moisture and form into lumps in the salt cellar Messrs Arthur and Co (69, Berners street, London, W) exhibited a number of interesting pharmaceutical preparations amongst which was "bromaurum," a compound of gold, arsenic, and bromine that has been used with advantage in some cases of nervous diseases.

Next week we propose to give a brief description of some of the more important exhibits coming under the categories respectively of surgical and sanitary appliances, together with a few miscellaneous exhibits of interest to the profession

(To be concluded)

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF COUNCIL.

OF the three members of Council whose terms of office have expired Mr. A. Willett and Sir Frederick Treves, Bart, K C V.O., C B., do not intend to offer themselves for re-election, but Mr. H. T. Butlin will apply once more The only other candidates of whom we have heard are Mr. Clinton T. Dent and Mr. A A. Bowlby, C M G. The nomination paper of any other candidate must be received at the College not later than Monday, June 8th. The election will be held on Thursday, July 2nd.

ANNUAL MEETING OF FELLOWS

A meeting of the Fellows of the College will be held on Thursday, July 2nd, at 5 30 P M. Any motion to be brought forward must be received by the secretary not later than June 11th Unfortunately, no meeting of Fellows has been held for several years as a quorum has not been present. We hope that some motions of importance may be brought forward at the ensuing meeting so that a quorum may be obtained.

ASYLUM REPORTS.

Surrey County Asylum, Brookwood (Annual Report for 1902) —The average number of patients resident during the [illegible] ales The [illegible] 157 males [illegible] ions. Mr. [illegible] ates in his report that the type of insanity, especially among the female admissions, "showed no improvement as regards curability from that observed of late years." Only 30 per cent of the admissions were deemed to possess a fair chance of recovery More than 25 per cent were over 50 years of age and 64 of the 335 admissions had suffered from previous attacks of insanity. 37 were epileptic and 15 were the subjects of general paralysis of the insane. Two female patients were admitted whilst pregnant and were safely delivered during the year, the children being subsequently removed by the friends Congenital mental defect or a hereditary predisposition to insanity was found to exist in 32 per cent of the admissions The number of patients discharged as recovered during the year amounted to 91—viz, 47 males and 41 females, or 8 8 per cent. of the average number resident The deaths during the year amounted to 93, or 8·9 per cent. as calculated on the same basis Of the deaths five were due to pneumonia, six each were due to renal disease and general paralysis of the insane, eight to pulmonary tuberculosis, nine to cardiac disease, 10 to epilepsy, 11 to senile decay, 14 to organic brain disease, and the rest to other causes. "Of the 1070 patients remaining in the asylum at the end of the year," adds Mr. Barton, "hardly 5 per cent. were deemed curable. A great many were old and feeble" 127 were epileptic, 22 were sufferers from general paralysis, and 104 were idiot or imbecile. Although influenza was prevalent and caused at times considerable inconvenience when the nursing staff was attacked the general health throughout the year was good and the death-rate was below the average. Owing to the prevalence of small-pox and the occurrence of cases in neighbouring towns the asylum was closed to visitors from February to September and all the members of the staff who required it were revaccinated. There were only two serious casualties among the patients during the year, both being cases of fracture of bones due to accidental falls. Many alterations and additions were made to the buildings during the year. The Commissioners in Lunacy state in their report that the asylum continues to be maintained in excellent order, that the wards were very clean and comfortable, that the furniture and bedding were in good condition, that the patients were orderly and well behaved, and that the medical case books were well kept. The committee of management states in its report that the weekly charge of maintenance of the patients was 12*s*. per head. A new chapel for the patients was opened on Dec. 15th. A new reservoir capable of storing 750,000 gallons of water was nearly completed at the end of the year and has since been filled. The sum of £2500 was authorised to be spent in connexion with a central boiler house and the work was practically completed by the close of the year and within the expenditure authorised.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8662 births and 4307 deaths were registered during the week ending Saturday last, May 30th. The annual rate of mortality in these towns, which had been 15 9, 15 4, and 15·5 per 1000 in the three preceding weeks, declined again last week to 14·9 per 1000. In London the death-rate was 13·9 per 1000, while it averaged 15·3 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 7·2 in Wallasey, 8·0 in Hornsey, 8·2 in Handsworth and in Kings Norton, 8 5 in Croydon, 9 1 in York, 9 9 in Tynemouth, and 10 1 in West Hartlepool; the highest rates were 19 8 in Liverpool, 19·9 in Sunderland, 20 3 in Huddersfield, 20 4 in Merthyr Tydfil, 21 0 in Rotherham 22 1 in Rochdale, 23 0 in Manchester, 23 6 in Burnley, and 26·9 in Middlesbrough. The 4307 deaths in these towns last week included 434 which were referred to the principal infectious diseases, against 457, 428, and 461 in the three preceding weeks; of these 434 deaths 136 resulted from measles, 101 from whooping-cough, 65 from diarrhoea, 50 from diphtheria, 38 from scarlet fever, 25 from "fever" (principally enteric), and 19 from small-pox. No death from any of these diseases was recorded last week in Bournemouth, Northampton, Devonport, Kings Norton, Smethwick, Derby, Bootle, York, West Hartlepool, Tynemouth, or Newport (Mon.); while they caused the highest death-rates in Leyton, Hanley, Wolverhampton, West Bromwich, Coventry, Nottingham, Wigan, and Middlesborough The greatest proportional mortality from measles occurred in Walthamstow, Wolverhampton, West Bromwich, Coventry, Nottingham, Wigan, Middlesbrough, and Swansea; from diphtheria in Southampton and in Hanley; from whooping-cough in St. Helens, Oldham, and Rochdale; and from diarrhoea in Wolverhampton and Warrington. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns Of the 19 fatal cases of small-pox registered in these towns last week four belonged to Liverpool, three to Leeds, two to Leicester, two to Manchester, two to Hull, and one each to London, Willesden, Oldham, Burnley, Bradford, and Newcastle-on-Tyne The number of small-pox cases under treatment in the Metropolitan Asylums hospitals, which had been 60, 60, and 64 on the three preceding Saturdays, had declined again to 60 on Saturday last, May 30th, 10 new cases were admitted during the week, against 17, seven, and 19 in the three preceding weeks. The number of scarlet fever patients under treatment in these hospitals and in the London Fever Hospital at the end of the week was 1771, against 1720, 1756, and 1759 at the end of the three preceding Saturdays; 225

from the operation. I graduate the width of the strip to be removed according to the severity of the signs present (rarely exceeding six millimetres) and I make a point of removing all the subconjunctival tissue right down to the sclerotic and of dissecting up the flap as close to the cornea as possible. When only a small patch of pannus remains at one point I do a partial peritomy there. Should the result of the first operation not be as complete as one could wish, the circumcorneal tissue may be carefully destroyed at a subsequent sitting with the actual cautery. When a few large feeder-vessels can be distinctly traced into the still persisting area of vascularisation, I prefer gently to pick these out with the cautery for a few millimetres along the length of each. I never find chloroform necessary except in nervous children.

I am, Sirs, yours faithfully,
R. H. ELLIOT, M.B., B.S. Lond., F.R.C.S. Eng.,
Captain I.M.S.

Edinburgh, May 31st, 1903.

THE RETARDED PULSE WAVE IN AORTIC REGURGITATION.

To the Editors of THE LANCET.

SIRS,—If some physiologist of repute will assure me, either through your pages or in private, that the tracings published by Dr. Walter Broadbent in THE LANCET of May 23rd, p. 1443, represent anything definite I may then congratulate him on having come to the conclusion that the pulse in aortic regurgitation is not "always retarded or delayed"—a distinct statement made by Sir William Broadbent from which he cannot extricate himself. I am afraid that my critics do not realise that the tracings I have given are of a totally different standing; they will pass muster in any first-rate physiological laboratory and they are in themselves the clear evidence of what goes on. Not so my comments upon them. But as to the question asked by Dr. Broadbent at the conclusion of his communication, I might be permitted to call his attention to the explanation which I have given[1] of the slowness of propagation of the wave in aortic regurgitation compared with the high velocity of the wave created by *impact* when the valves are intact.

I am, Sirs, yours faithfully,
PAUL M. CHAPMAN, M.D., F.R.C.P. Lond.,
Physician, Herefordshire General Hospital.

May 23rd, 1903.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

To the Editors of THE LANCET.

SIRS,—In my letter which you published in THE LANCET of May 9th, p. 1328, I inadvertently stated that I paid £10 10*s.* for the primary certificate of Fellowship which purported to grant exemption from the subjects of the Primary Fellowship Examination; this should have been £15 15*s.* Also, the number of successful Fellowship candidates should have been 51 out of 52 persons who presented themselves at four successive examinations. In answer to Dr. G. Fleming of Ombersley, whose comments on my letter appeared in THE LANCET of May 23rd, p. 1477, I have to state that the Executive Committee of the General Medical Council did me the courtesy of considering and placing my report of the illegal examination on their printed minutes and transmitted a copy of the same to the President, Vice-President, and Council of the College "for their information." In a letter dated May 26th, 1903, the Registrar of the General Medical Council informs me "that the Council had reason to believe that a minute on the subject was sent by the Royal College of Surgeons in Ireland to the Privy Council." It is evident, therefore, that the Privy Council for Ireland, to whom I also reported the matter, has not been negligent.

Although Section XXVI. of the Medical Act, 1858, gives the General Medical Council the power of erasing higher qualifications from the Medical Register, further action on the part of the Council it would be unreasonable to expect, for it must be recollected that although the Irish College of Surgeons has only one accredited representative on the General Medical Council, Sir Charles Ball, it has in reality three members of the body corporate to espouse its interests, for the representative of the University of Dublin and the Direct Representative for Ireland are also members of the Council of the Royal College of Surgeons in Ireland. This circumstance, indeed, may be taken as a plea against Direct Representatives being members of the governing bodies of universities or colleges, as dual interests are obviously against impartial representation of the already too feebly represented general practitioner.

Referring to the refusal of the College of Surgeons to give a Licentiate a copy of the College by-laws, may I now place on record my sense of the untenable position the College is now placed in should it have reason to criticise the professional deportment of a Licentiate to whom it so openly refused their by-laws by "the advice of their solicitor?" Indeed, its criticism of any Licentiate's conduct now could hardly have other than ludicrous effect, considering the unfortunate manner in which they themselves are shown to have neglected their own charter responsibilities. The Royal College of Surgeons in Ireland has now been given ample opportunities of refuting any false statements I have made. Its irregular higher examinations I have shown up in the face of great opposition. In silence it has accepted the only verdict that can now occur to your readers. In concluding, therefore, this correspondence I take the opportunity of returning you my heartiest thanks for so kindly placing your columns at my disposal and I recognise in such editorial courtesy a continuity of that same public spirit which actuated the great Wakley, where abuses were to be corrected or grievances were to be redressed.

I am, Sirs, yours faithfully,
May 30th, 1903. S. WESLEY WILSON.

ACUTE AMAUROSIS FOLLOWING INFANTILE CONVULSIONS.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 23rd, p. 1476, Dr. George Carpenter was good enough to comment upon some of the points raised by us in our paper under the above title.[1] Will you allow us to make one or two remarks in answer to his criticisms? In our paper we brought forward facts to show that a temporary amaurosis sometimes follows severe attacks of infantile convulsions and we sought to distinguish this group from the better known group of cases of amaurosis which follows an attack of posterior basal meningitis. In the former or post-eclamptic group we suggested that the blindness was due to a discharge from the visual centres followed by a condition of anæsthesia.

We need hardly say that we are conscious of the difficulties attending the diagnosis of the cause of the attacks of infantile convulsions in many instances and also that meningitis or a local encephalitis may be easily overlooked during infancy, especially in its initial stages. But putting doubtful cases on one side and taking the typical cases to which we called attention and which came under our own observation we cannot agree with Dr. Carpenter if he thinks that these were in reality cases of meningitis. Infants commencing with meningitis may or may not have convulsions, but no one can pretend that meningitis is a common cause of convulsions; indeed, the whole history of eclampsia and epilepsy disproves this. Surely because a neurotic infant has a feverish attack and severe convulsions ending in recovery we are not justified on such symptoms alone in diagnosing meningitis, even though the attack may have been followed by a fleeting amaurosis. Certainly, as a rule, if meningitis commences with convulsions the more characteristic symptoms of cerebral disease follow; they do not begin and end with fever, convulsions, coma, and recovery.

The pathology of the temporary blindness, hemiopia, aphasia, or paresis which sometimes follows convulsions or epileptic attacks is far from certain; there may be punctiform hæmorrhages, toxin poisoning, or, as we suggested as a cause for the amaurosis, a condition of exhaustion following discharge. That the more lasting hemiplegias or other paralyses which are associated at times with convulsions or whooping-cough, either one or both, are due to a meningeal hæmorrhage resulting from the stress and strain consequent on the convulsions and respiratory spasm is, we think, very probable and it is quite possible that the temporary loss of function which takes place may be due to a similar cause. With regard to another point raised as to the condition of the pupils and their reaction to light, our own experience is that in the early stages of amaurosis following undoubted cases of post-basal meningitis in infants the pupils are dilated and sluggish or do not react at all; later, as sight returns, the pupils react normally. This, however, does not seem to agree with the observations of some others. In our own cases of post-eclamptic amaurosis the pupils were active from the first.

"OPTICIANS" AND SPECTACLE PRESCRIBING.

To the Editors of THE LANCET.

SIRS,—I have read with interest your leading article under the above heading in THE LANCET of May 9th, p. 1312. The sight-testing scheme of the Worshipful Company of Spectacle Makers is so much in the air at present that I do not propose to discuss it, but I do ask you to allow me to say a few words on behalf of the optician, as some of your statements are liable to misinterpretation. I do not for a moment wish to belittle the work of the ophthalmic surgeons of the present day, but that those of former years were not above giving the optician his due there is clear evidence.

You say that before the days of Brewster there was no common knowledge of the function of accommodation and you credit Young with the discovery of astigmatism. Young claims the discovery of the function of accommodation also. As a matter of fact, he did not discover either of these things; he simply quoted what was common knowledge at the time. Young, who was then a student aged 20 years, read a paper before the [illegible] May 30th, 1793, entitled "Observat[illegible] *he announced* that he had discovered the muscularity of the crystalline lens. This so-called discovery was also claimed by the celebrated John Hunter, whose lectures Young was attending at the time. Young does not appear to have been imbued with the courage of the average discoverer, however, for he shortly afterwards abandoned the idea in a lecture at Göttingen, only to take it up again at a later period.

I discredit Young's discovery because on turning to an "Essay on Vision" by George Adams, the optician of Fleet-street, printed and published in 1792 (the year before Young's lecture), I find that Adams had a very clear notion of the function of accommodation and his reasonings are so good that they are quoted by leading oculists for many years after, such as Dr. Kitchener in 1826, Dr. Middlemore in 1835, and Dr. John Stevenson, oculist to the King, in 1834, who in his book, "Weakness of the Sight," advises his fellow practitioners to read the essay of George Adams the optician. To go back further still, Emerson the mathematician in his "Elements of Optics," published in 1768, says: "Tho' men may see distinctly at different distances by *altering* the *position* and *figure* of the *crystalline*, yet they can only see distinctly within certain limits and nearer than that objects appear confused."

As late as 1846, in a "Treatise on the Eye," Dr. W. C. Wallace speaks of accommodation being caused by the external muscles, advises people to defer wearing glasses as *long as possible,* and *recommends medicine as a substitute* for spectacles, and to this work there is a recommendatory notice by Sir David Brewster. Contrast this with the clear statement of Coddington who certainly was not a medical man. In an "Elementary Treatise on Optics" dated 1825 he says: "By means of a certain muscular mechanism which increases or diminishes at pleasure the convexity of the crystalline the form of the eye is modified so as to throw on the retina distinct images of all objects between very wide limits."

The reluctance of the medical profession to adopt the correct theory of accommodation by alteration of the crystalline is further shown by Dr. F. H. Butt who in 1847 still sticks to the notion of contraction of the pupil. I think this disposes of Young's discovery of the theory of accommodation, and I am afraid that he cannot in the face of his own statement be given much credit for originality in regard to astigmatism, for the following is a quotation from his miscellaneous works edited by George Peacock, M.D. *After describing the effect of the difference of focus* in the two meridians of the eye, he says: "On mentioning this circumstance to Mr. Cary the optician he informed me that he had *frequently taken notice* of a similar circumstance; that many persons were obliged to hold a concave glass obliquely in order to see with distinctness, counterbalancing the too great refractive power of the eye in the direction of that inclination and finding but little assistance from spectacles of the same focal length." It is tolerably clear from this that Cary the optician knew as much about astigmatism as Young did, particularly when the latter goes on to say, "The difference is *not in the cornea*, for it exists when the effects of the cornea are removed by immersing the eyes in water."

Then for the final discovery of the method of adapting cylindrical lenses to correct astigmatism, probably one of the most beneficial inventions of the nineteenth century, we have to thank Professor Airy, not a member of the medical profession, and even after this discovery it was not customary among oculists to prescribe cylindrical lenses until Andrew Ross, Dixey, and other opticians had become expert in making the lenses and correcting the defect. No suggestion ever appears to have been made by a medical man as to how the defect should be corrected; the very name was given to it by a parson, the Rev. Dr. Whewell.

That the opticians frequently had to correct the oculists' prescriptions in those days is shown by the fact that Dr. Harrison Curtis in his work on "Diseases of the Eye" published in 1833, has to chide his fellow physicians for prescribing amber lenses, quoting Peter Dollond the optician as his authority that they were injurious. I could carry these quotations on indefinitely, but think I have given sufficient to prove that the optician had a fair claim to knowledge in the old days and it is certain that the study [illegible] to pass the examinations of [illegible] day will not tend to lessen either his knowledge or general intelligence and the time is not far distant when ophthalmic surgeons will recognise that the opticians are their best friends, because the knowledge that they are acquiring will enable them to recognise disease in cases which now only come under the surgeon's notice when too far gone to remedy.

I am, Sirs, yours faithfully,
May 25th, 1903. JAMES AITCHISON.

To the Editors of THE LANCET.

SIRS,—I believe it to be contrary to your usual custom to publish in your columns a letter from a non-medical correspondent, but I trust that an exception will be made with this which refers to the leading article that appeared in your issue of May 9th, p. 1312, entitled "'Opticians' and Spectacle Prescribing." My letter, if published, may possibly tend to have some effect towards clearing a somewhat cloudy atmosphere and I am sure that the opticians who possess the diploma of the Worshipful Company of Spectacle Makers have an earnest desire to work in harmony with the medical profession.

All discoveries in optics have been made by opticians—whether medical men also or not is beside the question—and although discovery by one does not confer a privilege on another, yet if it did the application of lenses so as to alter the course of light which enters the human eye, would pertain to the optician, medical or other, and certainly not, I submit, to the physician *per se* who, indeed, may not be an optician at all. The adaptation of glasses for visual errors, being neither surgery nor medicine, has always been the work of non-medical opticians and so long as exact knowledge in matters optical was rare there seems to have been no opposition to it on the part of the medical profession. The question really at issue is simply whether it is better that spectacles should be sold by those who have a knowledge of optics or by those who have not.

That there has been an enormous increase in the number of glasses used within late years is an undoubted fact, this [illegible]ed knowledge and better procedure on [illegible] I do not [illegible] in the use [illegible] people at large. And the more the use of spectacles is appreciated by the public the greater the number of those who consult the oculist. Moreover, while the dealer who sells spectacles as he would pounds of sugar will supply them to all and every-one he who understands his work will at once recognise those cases which lie outside his province and refuse then to supply glasses except under the prescription of the oculist. I do not think that I exaggerate in saying that the optically educated optician will refer a dozen cases to the medical man while the optically uneducated optician will refer one.

And it must be obvious that it is impossible for the spectacle-vendor to know whether there be a diminished visual acuity or symptoms suggestive of serious muscular trouble or of disease or that the application of a mydriatic seems desirable, or that the condition seems complicated, unless he does follow a proper routine when a customer comes to him for optical aid.

Your article admits that "in the great majority of cases reading spectacles can be safely and well supplied by rule of thumb without further examination than can be accomplished by any of the ordinary forms of optometer." Since this is admitted, then surely must be the adaptation of distance glasses, for whatever may be the error of refraction in near vision such must also exist in distant vision; emmetropia being an exceptional condition, of course the emmetropic presbyope is a rarity and even he would, later on, become ametropic. The optician who does not test sight cannot know to what cases he may safely supply glasses and to what cases he should not; again, if he is able to discriminate by proper testing between the two, then surely he must be in a position to supply the correction where there is no indication of any trouble beyond that of uncomplicated erroneous refraction. You say that in consulting a medical man there is an "insurance against the existence of any actual or incipient disease which the spectacle-seller would be liable to overlook." This is indeed a fact, and it emphasises the great necessity for the education and certification of the refractionist in the work in which he is daily engaged.

Technically educated opticians now begin to recognise their own sphere and that of the medical man and this obtains to an extent already out of proportion to what was the case before the Spectacle Makers' Company's scheme came into existence. The difference in this respect between those opticians who have and those who have not yet associated themselves with the Spectacle Makers' Company is very marked. The principal point at issue in the optical world at this moment is whether the Spectacle Makers' Company shall crown their efforts for safeguarding the public and regulating the status of the optical industry by adding to their present examination one which includes spectacle-fitting or sight-testing. This suggestion, I venture to submit, ought to receive the highest encouragement from the medical profession as a step in the right direction for the benefit of all concerned—the public, the trade, and the profession itself. The present examination of the company only covers the subject of applied optics up to a stage which is short of the adaptation of glasses, while at the same time fully 90 per cent. of the diploma holders are daily engaged in this work. It is work needed by the public and was a prerogative of the industry, indeed, for centuries before the company undertook their modern system of examination. It must, then, be only right in the interests of everyone that the diplomates of the company should show by the ordeal of a proper examination that they possess the necessary information—not only an acquaintance with what they may and should do for the correction of optical visual defects but an acquaintance equally with the corresponding limitations, a sufficient knowledge of those circumstances under which medical treatment or the advice of an oculist may be necessary.

I am, Sirs, yours faithfully,

May 18th, 1903. LIONEL LAURANCE.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague Epidemic.—The Loss of Life from Wild Animals.

THE outbreak of plague for this season in India has passed its period of highest mortality and is now subsiding. In the Madras Presidency, which has never returned more than a few hundred deaths in a week, the mortality has sunk to 24, but in the Punjab, where the outbreak was the latest to develop, the deaths last week were 16,212. In the Bombay Presidency, where we have been accustomed to note thousands of deaths a week for a very long time past, the weekly record has sunk to 1242. In Bengal also the last return shows only 351 deaths and the recrudescence in Calcutta has nearly died out. Bombay city and Karachi are still suffering severely and 1160 deaths occurred last week in the United Provinces. The total mortality throughout India for last week was 20,264 as compared with 24,335 for the previous seven days and with 28,146 for the week before that. Taking the figures generally it is to be noticed that the outbreak has developed later in the season and has lasted longer into the hot weather. This, curiously, seems to be the feature of each recrudescence as compared with its predecessor. In Calcutta, however, so regular has been its incidence that the number of deaths for any particular week can almost be calculated beforehand. Another feature worth noting is the similarity in the number of deaths for each outbreak in certain places. Bombay city has had about 25,000 deaths each season, Calcutta about 10,000, but other places have varied considerably.

The Loss of Life from Wild Animals.

The destruction of life in certain parts of India by wild animals can only be emphasised by recording figures. In the Central Provinces alone 513 human beings were killed by wild beasts and 1304 by snakes during the past year. As a recent writer has endeavoured to minimise the work of the Pasteur Institute at Kasauli it may be worth mentioning that from this one district 56 people died from rabies after bites received from jackals. This danger exists over the greater part of India and the total mortality from rabies is probably considerable. The great mortality from snake-bite indicates the necessity of a more wide distribution of antivenene. The Jubbulpore district stands out as in particular danger from snakes. Over and above this destruction of human life something like 12,000 domestic animals were killed by snakes in the Central Provinces alone—a pecuniary loss which the sporting instincts of Europeans and the rewards for natives do not seem to prevent.

May 16th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Walk from Manchester to Southport.

THE example set by the recent walk from London to Brighton has soon been followed by a Manchester to Southport walk. Whether this is the result of emulation or merely an example of the imitative instinct existing in man and some of the lower animals it is scarcely worth while to inquire, but it is comforting to know that the art of walking is not to get lost. Many of us would also commend these walking contests as being harmless to the ordinary users of the King's highway. The main roads of the country, even in comparatively remote districts are now so dangerous that timid or nervous people are afraid to venture on them. They have got accustomed to the comparatively innocent cyclist but they look with dread at the motor-cycle as it rapidly approaches with its tiresome knock, knock, knock—which, however, must be looked on as tending to safety—and with horror at the motor car with its goggled, veiled, and dust-begrimed occupants leaving their taint behind them as refreshment for those who have escaped destruction. Seriously, however, the roads are being made almost unusable by ordinary people either for walking, riding, or driving, for not only is the danger by no means imaginary as the daily papers show, but the dust nuisance is at times almost intolerable, and, of course, by no means innocent of danger. Possibly the selfish craze for immoderate speed on the ordinary high-roads may subside by-and-by either as the result of convictions for manslaughter or on more æsthetic grounds. In the meantime one turns with some satisfaction to the record made by 100 or 101 men who walked the 41½ miles on May 23rd between Manchester and Southport. The winner covered the distance in 7 hours 11 minutes 8 seconds, while the second man was only two seconds later, and the third man was not far behind. The others tailed off for nearly three hours, but the last got in just under 10 hours. Two sisters 18 or 20 years of age, living in Moss Side—from which district, curiously enough, the first and second of the men hailed—started on their own account rather earlier than the men and walked the whole distance and said that they were in no way exhausted by their 10 hours' continuous walking. It does not appear that there had been much special training among the competitors but most of them were fond of various forms of exercise. "There were solicitors, stockbrokers, accountants, medical men, chemists, bank clerks, warehousemen, a Walkden collier, a

Salford policeman, young men with smooth chins, business men well advanced in the forties, and a wrinkled veteran of the Indian mutiny." It speaks well for the endurance of the men that at the dinner in the evening they appeared very little the worse for their walk. The mayor of Southport presided and presented a silver cup, photographs, and a medal to the winner and medals to the second and third and promised mementos to the two young ladies who on their arrival in Southport were at once invited to the dinner. Within reasonable limits the resuscitation of walking as an exercise is desirable, but it seems as if in these days nothing is thought worth doing for its own sake but only in competition with others and for the sake of making a record. In one long-distance walk those engaged, who must be "amateurs"—a word now of somewhat doubtful meaning—"may be paced by cyclists." These contests seem to be springing up like mushrooms all over the country and as in most cases the competitors are accompanied by cycles and motor-cars there will be an accompaniment of noise, dust, and smell which some found sufficiently trying on this recent occasion Some thought cramp in the thighs would have stopped them, others suffered from "stitch," and sore feet were not rare. The winner is said to be "a total abstainer and a non-smoker only when he is in training," the second being a total abstainer and non-smoker.

The Manchester Infirmary.

Some members of the infirmary board are spending the Whitsuntide holidays in visiting the most important hospitals in London, Scotland, and elsewhere. The knowledge which they thus obtain will help them considerably in the great work they have in hand.

Shell-fish and Sewage.

Looking at the expanse of the Duddon sands one would not associate them, without some evidence, with the indictment recently found against them. "Owing to the many cases of poisoning by eating shell-fish contaminated with sewage matter," the Millom urban district council had a number of mussels and cockles taken from the sands analysed. Dr. R. T. Hewlett, of King's College, London, examined 36 specimens and found them "swarming with bacteria" and said that the beds must be seriously polluted with sewage. The samples were got from three different places, one bed being "12½ feet under water at low water." This is without much doubt an illustration of the state of things all round our coasts. "It was decided to issue notices to the public warning them against eating this shell-fish." As long as our present mode of disposing of the sewage of seaside places is continued we shall have constant repetitions of the above story. It is the readiest and least troublesome method to turn the sewage right away into the sea, forgetting the penalty to follow in the sickness and loss of life entailed, in the injury to the local reputation sure to follow, and when the fact as to the danger of sewage poisoning is known the loss of a valuable food-supply and the consequent suffering and privation of the mussel-gatherers. The return of sewage to the land is the unattained, but surely not unattainable, end to be sought and, at all events, it is quite clear that sewage ought not to be so disposed of as to make the eating of a cockle, a mussel, or an oyster, or even the humble periwinkle, an operation to be performed at the risk of life.

The Dangers of Electricity.

About three o'clock in the morning, fortunately, of May 24th a serious explosion took place in Manchester, wrecking the basement of one warehouse and followed by a fire in the cellar of another next door. It was found that there had been a fusion of electric wires, but whether in these premises or in the street cables does not seem to be certain. Before a proper inspection could be made an explosion "shattered the doors, windows, railings, woodwork, and glass" in one basement and "fragments of timber were hurled across the street with sufficient force to break in a door on the opposite side of the road. Three large stone steps about two yards long and weighing five or six hundredweight each were shifted about three yards and piled one above the other," while other damage was also done "The cause of the explosion and also of the fire are not at present explainable." Such is the usual statement about these too frequent occurrences, but it is pretty certain that they would not happen if sufficient care were taken. Knowing though they do the enormous power of the agent which they are endeavouring to control and to break in to our service, the electrical engineers from their familiarity with the matter may perhaps forget that their supposed servant will, if they are not very careful, turn out to be master and it may be doubted if the necessity for extreme care as to fittings and insulation is always realised by them and by the workmen employed by them.

"A Doctor's Error."

The above heading occurs over the report of an inquiry into the cause of death of a member of the town council of Blackburn which was held on May 26th. His medical attendant made up for him a bottle of medicine and a liniment of aconite, belladonna, and chloroform, and through [illegible] "he must inadvertently [illegible] for the label he was [illegible] verdict of 'Death from misadventure' and expressed the opinion that liniment should be placed in bottles of a distinctive shape and labeled 'poison.'" They condoled with the bereaved family and the foreman referred to the medical attendant's manly admission of his serious error saying that his conduct had not been evasive but open from beginning to end.

June 2nd.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Pontypridd Workhouse Extension.

IN spite of the good wages and regular employment which have prevailed for several years past in the districts which comprise the Pontypridd Poor-law union it has been found necessary to increase the workhouse accommodation. The present workhouse, which was erected in the year 1865 and has been from time to time enlarged until there is now room for 320 inmates, is situated in the town of Pontypridd on a site where there is no adjacent land available for further additions The total population included within the area of the union is over 200,000 and 120,000 of these reside in the two Rhondda valleys, the nearest portion of which is distant about two miles and the furthest about 12 miles from the workhouse. The board of guardians very properly, therefore, decided to establish a secondary workhouse in the centre of the large Rhondda population and within the next few weeks buildings will be brought into use which have been erected at a cost of £12,000 for the accommodation of 60 men, 30 women, and 12 married couples The institution includes a house for the master with a board-room and extensive store-rooms, four separate pavilions, and a lodge. Three of the pavilions are two storeys high and are arranged on identical lines. On the ground floor there are two day-rooms, a large kitchen and pantry, a bath-room with two stoneware baths, and a lavatory with a range of four basins. On the first floor there are three wards to accommodate 11, 11, and eight persons respectively, a nurses' bedroom and sitting-room, four water-closets, and two slop sinks The site of the buildings on the hillside lends itself well to the provision of fire-escapes from the upper floors of the pavilions where in the two largest wards a door opening outwards gives exit to a bridge terminating on the slope of the hill. The fourth pavilion is one storey high and is for the accommodation of 12 married couples, each of whom has a bedroom measuring 15 feet by 12 feet in which there are two fixed cupboards, suitable hanging pegs and furniture, and a fireplace with a Dutch oven. For the use of each six couples there are two baths, two lavatory basins, two water-closets, and a large kitchen centrally situated; in this pavilion are a double-bedded room for nurses and a large sitting-room. Some care has been taken in the design of these buildings in the direction of avoiding dust-collecting ledges; for example, there are no architraves to the windows, although they are provided round the doorways while there are several exposed beams which will be difficult to keep free from dust. The buildings are constructed of local stone with pebble stucco; the inside walls are covered with a smooth adamant cement. Taken as a whole, the Pontypridd board of guardians may be congratulated upon the acquisition of a well thought-out and excellently planned institution.

Llanelly Cottage Hospital.

The Llanelly Cottage Hospital, which was established in 1867 and has now accommodation for 30 patients, is in a much more prosperous condition than it has been for many years. The committee of management is composed jointly of employers and workmen and of the £1500 contributed during the past year towards the funds of the institution no less a sum than £621 was obtained from periodical collections made in the works of the district. A further sum of £400 was the result of a fête organised by Mr. Studt, a popular Welsh showman, through whose coöperation many hospitals in the Principality benefit every year.

Weston-super-Mare Children's Convalescent Home.

This excellent institution has now been established about nine years and is for the benefit of children attending the public elementary schools in Bristol and of those who have been inmates of the Bristol hospitals. At the annual meeting which was held on May 29th it was stated that 324 children had been in the home during the past 12 months and that the total expenses had been only £547.

New Asylum for Newport.

A new asylum is being erected for the Newport (Mon.) corporation on a site near the river Usk at Caerleon and the foundation stone was laid on May 27th in the presence of a large gathering. The asylum when complete will accommodate 368 patients (184 of either sex). At present it is intended to proceed with the erection of six blocks of the building.

June 1st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow Obstetrical and Gynæcological Society: Visit of Dr. Howard A. Kelly.

MEDICAL practitioners in Glasgow and the West of Scotland will be interested in hearing that Dr. Howard A. Kelly of Baltimore, the honorary President of the society, is to visit Glasgow and to deliver the presidential address in the Faculty Hall on Wednesday, June 17th, at 8 30 P.M. The subject that he has chosen is one of general interest, the History of Appendicitis in Great Britain. All medical practitioners are invited. I understand also that the Edinburgh and Glasgow Obstetrical Societies are to meet in joint session in the same hall on the following day at 5 30 P.M., when Dr. Kelly will introduce a discussion on the Extirpation of the Uterus and Appendages in Serious Pelvic Inflammation, and the two societies are afterwards to dine together in the neighbouring Windsor Hotel.

Aberdeen University Medical Society.

The summer session of Aberdeen University Medical Society was opened on May 29th with a lecture by Dr. J. Marnoch on Recent Works and Opinions on the Etiology of Cancer. Professor J. T. Cash presided and with him on the platform were Dr. Angus Fraser and Dr. Ashley W. Mackintosh. The chairman congratulated the large number of members present on the continuance of their meetings in the summer time when there were so many attractions of other kinds. Dr. Marnoch needed no introduction to them. He knew his subject and was an excellent teacher. Dr. Marnoch then gave in review the work recently accomplished in connexion with cancer. Dr. A. Wolff had recently shown from statistics collected throughout Europe that high cancer areas were associated with (1) districts which were well wooded, especially if they were also well watered, a result in direct variance with statistics previously obtained from England and Wales; and (2) districts where much beer and cider were drunk—e.g., Bavaria and Lille. The deaths from cancer in the eight principal Scotch towns in 1872, with a population of about 1,000,000, were 445; in 1902, with a population of about 1,500,000, they were 1523; so that cancer was on the increase in spite of allowing for increased accuracy of diagnosis. The parasitic and the anti-parasitic views were then discussed and the lecturer showed that the bulk of evidence was against the disease being parasitic in origin. On the conclusion of the lecture Dr. Marnoch was heartily applauded. Dr. Fraser said that he had learned a good deal and had listened with the greatest pleasure and instruction to the admirable *résumé* on cancer from Dr. Marnoch. He had had the modesty not to refer to it, but Dr. Marnoch had done original work in the matter himself and was therefore all the more entitled to speak with some authority on the subject. He had pleasure in moving a hearty vote of thanks to Dr. Marnoch for his interesting and educative lecture. Dr. Marnoch, in replying, congratulated the society upon its vitality. The meeting terminated with a vote of thanks to the chairman, proposed by Mr. George Hall.

June 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Nursing Scandal at Granard Union.

THE prolonged inquiry by the Local Government Board into the state of things which prevailed in the union hospital at Granard has at last come to an end. After considerable delay the decision of the Board was recently conveyed in a letter to the guardians read at their meeting on May 18th. The letter stated that the evidence "revealed a condition of things regarding the provision made by the guardians for the care of the sick and infirm which may be described as shocking." It contains a long indictment of the guardians for their neglect and for their failure to support their medical officer in the reforms which he attempted to bring about. Their action in calling on Dr J. M. S. Kenny to resign because he would not permit a wardsmaid to do nursing duties after a trained nurse had been engaged, is described in the report as "a most improper attempt to intimidate an officer in the conscientious discharge of his professional duties." The report states that "the list of nursing duties that the nuns of Granard workhouse gave as outside their province as nurses in charge of sick wards came upon the Local Government Board as a surprise." Another meeting of the guardians took place on the 25th, when a letter from the sisters tendering their resignation was received. A committee of the guardians waited upon them and they consented to remain for the present in the workhouse provided that "the board would insist on Dr. Kenny not making use of insulting and abusive language to them in the interval and that a ruling to this effect was inserted in the minutes." A resolution to that effect was passed accordingly and subsequently it was resolved:—

> That having now heard the report of the Local Government Board in regard to the recent sworn inquiry—an inquiry which took up much time and cost so much to all parties—that the Local Government Board be requested to state why in framing their report they did not go into the real root of the evil, namely, the want of harmony between Dr. Kenny and the nursing staff, and that inasmuch as no improvements in the house can, in our opinion, stop this long existing friction, we now ask the Local Government Board either to go into the matter or give their reasons for passing it over.

The nursing sisters at Mullingar union hospital have since resigned in consequence of the action of Dr. Kenny and the Local Government Board but have agreed conditionally to remain in charge of the infirmary for one week.

Distinctions won by Students of Queen's College, Cork.

At the recent medical examinations at the Royal University two Cork students were particularly successful. At the second examination Mr. W. A M'Kee was awarded first-class honours and a first-class exhibition of the value of £25. No other student obtained honours or an exhibition at this examination. At the M.B., B.Ch., B A.O. degrees examination Mr. Norcott Harvey, also a student of the Cork College, was awarded first-class honours and a first-class exhibition of the value of £40. He was the only one of the candidates who won those distinctions. That means that in these two examinations students of Queen's College, Cork, headed the list. At the examinations at the Royal Colleges of Physicians and Surgeons of Ireland held about the same time another Cork student, Captain Dorgan, R.A.M.C., a candidate for the diploma in sanitary science, obtained first place in all Ireland and was awarded honours.

Dispensary Contest in the Ardee Union.

In THE LANCET of May 23rd, p. 1484, it was announced that on May 5th Mr. W. H. Crean of Dungarvan was elected medical officer of Drumconrath dispensary in the Ardee Union, co. Louth. The original salary was £120 per annum and £30 as medical officer of health. The two local men, in loyal adherence to the resolution of the local branch of the Irish Medical Association, declined to become candidates until the salary was raised to £200, the minimum suggested by that association. On May 14th, at a meeting of the county Louth branch of the Irish Medical Association, the following motion was unanimously passed:—

> That we, the members of the Irish Medical Association, reiterate our determination to adhere to the resolutions of the Irish Medical Association dealing with practitioners who take dispensaries under the stipulated salaries.

At a meeting of the Ardee board of guardians held on May 19th a letter of resignation was read from Mr. Crean. The Drumconrath dispensary is therefore still vacant after three attempts at an election. This is a great victory for the Irish Medical Association and is in favour of combination.

The Irish Medical Association.

The annual meeting of the Irish Medical Association is to be held in Enniskillen on Wednesday, June 17th, under the presidency of Dr. L Kidd, surgeon to the Fermanagh County Infirmary, and owing to the very keen interest aroused at present in the conflict between the Poor-law medical officers and the local and central authorities the attendance promises to be a record one. The following is the programme:—

own-hall, Enniskillen, at 2.15 P.M., Minutes of the meetings held on 1902. Report of the council and

Motions to be Brought Forward.

1. That the report of council and financial statement for the past

Proposed Scheme.

The Council recommend the following resolutions and invite discussion thereon:—

3. That the minimum salaries for dispensaries be £200; for workhouses, £120; or both combined, £300.

4. That medical officers in the Poor-law service be entitled, as a matter of right, to superannuation on the Civil Service scale.

5. That all medical officers in the Poor law service be entitled to four weeks' annual vacation in accordance with Article 28 of the Local Government Board rules; and that the payment of the locum tenens be as provided for by Section 5 in the Local Government Amendment Act, 1902.

6. That the fees for discharge of temporary duty be:—

	£	s.	d.	
Dispensaries	4	4	0	per week.
Workhouses	3	3	0	"
Both combined	5	5	0	"
Periods less than a week	1	1	0	per day.

7.

	£	s.	d.
stance			
...	3	3	0
ce up	2	2	0
(c) Between 8 A.M. and 8 P.M. and for any distance	2	2	0
... ...	2	2	0
... ...	1	1	0

Distance not to exceed in either case 12 miles.

8. Appointment of two auditors.

A banquet will be held in the same place in the evening at 7.45 P.M. and on Thursday, June 18th, an excursion will take place to Bundoran. The railway companies are issuing return tickets from all parts of Ireland available from June 15th to 18th inclusive at a fare and a quarter for all classes.

Medical Fees in Omagh Union.

In THE LANCET of May 23rd, p. 1465, reference was made to the extraordinary treatment of Dr. E. C. Thompson, M.P., by the Omagh guardians in having summarily dispensed with his services while acting for Dr. H. B. Fleming who was ill. Dr. Thompson demanded £12 12*s.* for his four days' attendance at the workhouse. At the meeting of the guardians on the 30th the clerk suggested that the guardians should offer Dr. Thompson £3 3*s.*, the amount he said required by the Tyrone Medical Association. The chairman said that in addition to tendering this sum they should add that they were sorry Dr. Thompson should feel that they did not treat him with the same courtesy that he expected.

Extraordinary Action of the Irish Local Government Board.

Dr. John Bolster having resigned the Tinahely dispensary, co. Wicklow, the Shillelagh guardians decided to increase the salary for the incoming medical man by £30, making it £150, instead of £120 as formerly, fearing they might not have applicants at the old salary. When asked to sanction this arrangement the Local Government Board refused to approve of the increase, as it understood that there was good private practice for a medical officer at Tinahely and that it saw "no reason to doubt but that a number of eligible candidates will offer themselves for the vacant dispensary at the existing salary and emoluments." The chairman of the board of guardians, when this communication from the Local Government Board was read, said he supposed that any expense they would go to in advertising the appointment at £120 a year without getting any replies would be borne by the Local Government Board. It is to be hoped that no medical man will apply for the post in order to teach the central authority (the Local Government Board) in Dublin a salutary lesson. Its action in this matter is most insulting to the medical profession and is extremely stupid when taken with the fact that it constantly replies to the demands of the Poor-law medical officers that it is no use agitating for higher salaries when on the occasion of any vacancy numbers apply at the old rates. The truth is that in Ireland at present the Local Government Board, from its want of pursuing a consistent policy, is being very greatly discredited.

Syphilis and Suicide.

AT the meeting of the Academy of Medicine held on May 19th Professor Fournier discoursed upon the question of suicide in syphilitic patients. He had had personal experience of 18 cases and many others had been observed by his colleagues. Professor Fournier has done more than anyone else to enlighten the public as regards the terrible dangers of syphilis He is anxious that this plague should be brought into the full light of day, for it is not made enough of. Syphilis, he added, requires a long and patient treatment, for it has terrible hereditary effects and causes veritable social ravages. The extremely active anti-syphilitic campaign initiated by Professor Fournier

any cure for the various manifestations of the disease, the knowledge of which makes them lose their courage; (3) nervous patients who kill themselves on learning the nature of their disease; and (4) those who discover their complaint on the eve of marriage and do not stop to find any other way of breaking their engagement. Professor Fournier implored all medical men to use great tact in announcing their diagnosis to nervous and impressionable subjects and reminded his audience that syphilis as a whole is one of the most easily curable diseases

Surgical Intervention in Pulmonary Gangrene.

For two successive meetings the Society of Surgery has been discussing the subject of pulmonary gangrene and the surgical relief of this condition. The first meeting was held on May 13th when M. Lejars related many cases occurring in his own practice in which he had interfered surgically. He reminded his audience that not all cases of pulmonary gangrene were fitted for operation. Interference should only be undertaken when the gangrenous foci were strictly localised and limited; moreover, stethoscopy by a trained ear was to be relied upon in diagnosis far more than any other method. Radiograp

most uncertain results. The

sufficiently healthy state to

a possible infection from the diseased side. As a rule the operation is easy, although sometimes difficult owing to the existence of multiple gangrenous foci. M. Lejars laid stress on one point in the technique of the operation—namely, that a large opening should be made in the thorax in order to have plenty of light and also that later the chest wall might easily fall in so as to fill up the void caused by the retraction of the pulmonary tissue. Although cases of cure by operation are not rare, yet they are not absolutely lasting. Statistics cannot yet be furnished of the frequency of relapses but they are fairly numerous. At the adjourned meeting held on May 20th M. Tuffier spoke. He agreed with M. Lejars, but he added that they must not forget that surgical interference only substituted artificial for bronchial drainage. If the latter were sufficient it was useless to interfere; if not, a free thoracotomy must be done, only as far as possible the operator should avoid opening the pleura. Prognosis varied in every case and depended mainly upon the cause of the gangrene. Interlobar pleurisy with superficial gangrene must be distinguished from pulmonary gangrene properly so called. It is true that the diagnosis between these two forms is difficult, but it should be made where possible, for the prognosis of the two is very different. It is important to ascertain whether the gangrene is accompanied by bronchiectasis, for in such cases complete cure is rare. M. Tuffier concluded by remarking that gangrene is sometimes due to a foreign body. He had seen two cases of gangrene following the removal of adenoid vegetation. In the one case he had had to open two interlobar abscesses and the patient recovered. In the other case there was a fœtid cerebral abscess and the patient died. In another case under his care gangrene was caused by a portion of the bone of a calf. M Tuffier opened and drained the abscess. The cavity, however, took eight months to close and the patient had constant cough. In 11 cases M. Tuffier had four deaths and seven recoveries. Of the deaths three were due to secondary hæmorrhage and the fourth to septicæmia. Of the seven recoveries two were complete and five were incomplete.

The Lady Minto Hospital Fund.

NOT long since the Countess of Minto invited a number of the business men of Ottawa to Government House, when she explained in an address what had been done in connexion with the Lady Minto Cottage Hospital Fund. The sum of $20,000 had been raised and with this sum the districts which were considered to be most in need of hospitals had been assisted. Ten hospitals are now in working order and four new ones will be opened shortly. There are now 68 nurses of the Victorian Order in active work, some being employed in hospitals and the rest in district nursing. The 18 towns that employed these nurses raised their funds locally to pay their salaries. Her Excellency pointed out that the central fund had been supported from three places—Montreal, Toronto, and Ottawa. This she considered unfair, as the scheme affected the whole Dominion. Her object is now to raise an endowment fund which will realise an income of $5000 per annum. Dr. T. Gibson of Ottawa, the honorary secretary of the Victorian Order, stated that it was the desire of Lady Minto to have the endowment fund raised before her departure for England. The capital sum aimed at was $123,000 and towards this end a few gentlemen of Montreal had already contributed $36,500. A committee of the business men of Ottawa was formed to commence the work of organisation and to secure subscriptions.

Tuberculosis Conference.

The Governor-General, Lord Minto, delivered an address at the third annual conference of the Canadian Association for the Prevention of Consumption held at Ottawa on April 15th. He stated that he believed that there were annually not less than 30,000 cases of consumption in the Dominion of Canada and that the number of deaths was about 9000. The association had performed a great service by drawing the attention of the public to the ravages of the disease. Dr. H. Beaumont Small of Ottawa read the annual report which dealt especially with the educational propaganda which had been carried on during the past year. In Canada out of 36 hospitals only 13 had special accommodation for the treatment of tuberculous patients. Dr. A. J. Richer of Montreal, honorary secretary of the Montreal League for the Suppression and Prevention of Consumption, which has lately been affiliated with the central body at Ottawa, read a paper on the Economic Aspect of Tuberculosis in which he estimated the annual loss to Canada from tuberculosis at $72,000,000, which was based on the deaths and sickness from the disease. He further contrasted the action of the Dominion Government in relation to its expenditure annually in the prevention of tuberculosis in the animal and human kind. While the Government had spent last year $1000 in the prevention of tuberculosis in the human being, it had expended nearly 40 times that amount in the same cause amongst cattle.

The Insane in British Columbia.

Dr. Manchester, the medical superintendent in charge of the provincial asylum for the insane at New Westminster, British Columbia, has issued his official report for the past year. The year commenced with 284 patients in residence in the institution and eight on probation. During the year 121 new patients were admitted, 95 males and 26 females. The increase in admissions as compared with the previous year numbered six, all males. The discharges numbered 61 and the deaths 26, these figures being almost identical with those of the previous year. The year closed with 16 patients still on probation and 311 in residence. Of the total number admitted 50·41 per cent. were discharged, not including the deaths, 24·8 per cent. recovered and 25·6 had not recovered. In some quarters it seemed to be the prevalent belief that the percentage of insanity was higher in the province of British Columbia than in any of the other provinces of the Dominion, but Dr. Manchester in his report disproves this and states that quite the reverse is true. The total number of insane in the entire Dominion of Canada according to statistics is 16,495, or 3·1 per 1000 of population. In British Columbia the total is 299, or 1 67 per 1000 of population, the other provinces being thus accounted for: Manitoba, 565, or 2·21; New Brunswick, 1054, or 3·18; Nova Scotia, 1392, or 3·02; Ontario, 7511, or 3 44; Prince Edward Island, 357, or 3·45; and Quebec, 5245, or 3·18.

Cases of Gastric Ulcer occurring in the Royal Victoria Hospital, Montreal, during the past Eight Years.

Dr. E. P. L. Cantlie, externe in clinical medicine at the Royal Victoria Hospital, Montreal, has published in the April issue of the *Montreal Medical Journal* an analysis of the cases of gastric ulcer occurring in that institution during the past eight years. During that period of time there were in all admitted to the institution 20,596 cases, of which number 85 were cases of gastric ulcer, three being in males and 82 in females. More than one-half of these were native-born Canadians, more than one quarter were born in Great Britain, while the balance came from the United States and other places. The ages varied from 17 to 70 years, the average being 27½ years. There were eight patients under 20 years of age and ten over 40. The most frequent time of all was the third decade, 49 out of the 75 patients where the age was recorded being between 20 and 30 years. 34 patients were servants, 14 were housekeepers, and only two gave occupations definitely as cooks. Anæmia was an associated condition in 42 cases. In five of the cases there were no prior symptoms relating to the stomach. Of the surgical cases all but one were admitted after perforation had occurred. These numbered eight, with seven recoveries. Of the 83 cases of which records have been kept, 39 are recorded as cured, 34 as improved, one is noted as unimproved, and in six the result is unrecorded. Two patients died, one from perforation and general peritonitis and the other from hæmorrhage. In this last case multiple erosions were found post mortem.

Typhoid Fever in the Royal Victoria Hospital, Montreal, in 1902.

Dr. Colin K. Russil, senior resident physician at the Royal Victoria Hospital, Montreal, has compiled for the *Montreal Medical Journal* statistics relating to the cases of typhoid fever occurring in that institution for the year 1902. In all there were 90 cases treated, 58 males and 32 females. Of these 75 were treated to a conclusion, 15 being still under treatment at the time the report was published. The average age of all the patients was 23 years, the youngest being three and the oldest 63 years old. Arranged in decades they are as follows: under 10 years, six cases; from 10 to 20 years, 19; from 20 to 30 years, 36; from 30 to 40 years, 11; from 40 to 50 years, one; and from 50 to 60 years, two. The largest number of cases were admitted during the month of August, there being 17 admissions during that month. The average day of disease on admission was the ninth. The average number of days in the hospital was 38·5. The average duration of fever after admission was 31·5 days. The longest period of fever after admission was 42 days. The shortest period of fever while in hospital was seven days, of which there were two cases. *Diarrhœa* was present at the onset of the disease in 33·3 per cent. Constipation was present at the onset of the disease in 48 per cent. Vomiting was present at the onset in 32·2 per cent. An Epistaxis was present at the onset in 18·6 per cent. The earliest eruption was present in 81·2 per cent. of cases. The earliest appearance of the rash was on the fourth day and the latest on the twenty-ninth day. In two cases the rash appeared only during the relapse. The average duration of the rash was 15 days, the shortest being three days and the longest 27 days. The Widal test was tried in all cases. It was negative in six. The test was tried in 39 cases on discharge; it was present in 35, absent in three, and doubtful in one. In one case it appeared on the fifth day. In another it was not present until the twenty-fourth day of the disease. It was present on the average on the thirteenth day. In 21 cases it was present on admission. There were four fatal cases recorded as follows: typhoid fever with perforation, operation, death; typhoid fever, perforation, and death; typhoid fever, toxæmia, intestinal hæmorrhage, extreme toxæmia, and death; and typhoid fever with purpuric eruption, toxæmia, and death.

The Proposed Dominion Medical Council.

The Quebec Legislature has rejected by a large majority the motion to ratify the Canada Medical Act, 1902, commonly known as the Roddick Law. This Act was procured from the Dominion Parliament after persistent and patient effort on the part of Dr. Roddick, M.P., for many long years. It was passed at the last session of that parliament on the understanding that before it became operable it must be ratified by the legislatures of the different provinces. Quebec has refused to do this and as a consequence Dominion registration has received a set back, but it is hoped only for a time. During the past few months amendments to the Act of 1902 have been agitated for in the province of Quebec and the question of asking for these was brought before the Montreal Medical Society, with the result that a special committee was appointed which made a report on March 31st last in favour of certain amendments, which report is said to have been adopted. It would appear that the great difficulty on the part of the province of Quebec is the desire of one of the universities of the province to extend over the whole Dominion its prerogatives which at present are confined to that province. In other words, the majority in Quebec would give the holder of a Quebec university degree in medicine the right without further examination to practise anywhere in the Dominion.' Their meaning is quite clear without quoting in full the proposed amendments. This does not suit the taste of the University of Toronto in the province of Ontario, and its medical faculty has prepared a memorandum calling attention to these proposed amendments to the Canada Medical Act which, if allowed to proceed further without opposition, would result in prejudicing the course of medical education in the province of Ontario. That the whole question will have to be thrashed out again before the provincial and national medical societies seems certain. All the other provinces have taken the necessary steps to have the Act ratified on the initiation of their respective medical councils, each of which has approved of such legislation. The College of Physicians and Surgeons of Quebec refused to recommend any ratification legislation to the Quebec House, hence the rejection of an independent motion.

Toronto, May 16th.

GLASGOW UNIVERSITY CLUB. — Mr. George Wyndham, M.P., Lord Rector of the Glasgow University, took the chair at the dinner organised by the Glasgow University Club (London) and held at the Trocadéro Restaurant, London, on May 29th. Among those present were the Earl of Lytton, Lord Shand, Professor A. C Bradley, Professor John Adams, Professor W. P. Ker, Professor J. M. Thomson, Professor J. H. Byles, Dr. Guthrie Rankin, Dr. H. Carmichael, Lieutenant-Colonel W. Babtie, V.C., C.M.G., R.A.M.C., Mr. Edmund Owen, and Dr. C. O. Hawthorne In giving the toast of "The University and the Club" the chairman said that he had received letters of apology for non-attendance at the dinner from Lord Kelvin, Lord Lister, Sir W. Gairdner, Sir W. Ramsay, and Professor Dewar. Continuing, the chairman said that it had been asked why the Glasgow University Club met in London; the answer was that London was the most appropriate place for such a dinner. That city had become the heart of a world-wide empire, of which no portion yielded so many servants to the State as the Scottish universities. Professor Bradley proposed "The Houses of Parliament," which was responded to by Lord Lytton and Mr. W. J. Galloway, M.P. In replying to the toast of "The Guests," proposed by Mr. J. M. Dodds, Mr. Edmund Owen said that Scotland, and Glasgow in particular, had supplied a great number of men of science. He thought that that was due to the splendid education in Scotland. The toast was also replied to by Mr. O. M. Drew, President of the Glasgow University Union. The toast of "The Chairman" was proposed by Mr. D. A. Dick, President of the Students' Representative Council, University of Glasgow, and after the chairman had replied the proceedings terminated.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WEDNESDAY, MAY 27TH.

The Council continued its proceedings to-day, Sir WILLIAM TURNER being in the chair.

After the confirmation of the minutes of yesterday's meeting,

Mr. BROWN said he wished the Council to go into *camerâ* at once. He wanted to call attention to a minute of the Executive Committee in regard to a matter affecting a practitioner about whom he had received a letter that morning.

The PRESIDENT: That is not the business before us to-day.

Mr. BROWN agreed that it was not but he wished also when *in camerâ* to put a question in relation to the business on the programme for that afternoon.

The PRESIDENT: You cannot alter the Executive Committe's minutes in Council, but I understand that you want to discuss a point about the first case on to-day's business programme before the parties to that case are called? Is the Council satisfied that it should be so?

No assent was given.

Mr. BROWN: Then I move formally that the Council go into *camerâ* before the parties in the first case are called.

Dr. BRUCE seconded the motion, which on a vote was rejected by 13 to 7.

The PRESIDENT asked that the parties to the case referred to should be called.

Dr. WILLIAM GEORGE NIALL, registered as of Kinkora, Dabdune-crescent, Guildford, M.D., Mast. Surg. 1886, R. Univ. Irel., who had been summoned to answer a charge formulated by the Council's solicitor, answered the call, accompanied by his counsel, Mr. BODKIN, who in reply to a question explained that he was appearing with Mr. Symmons, instructed by Mr. Kempson, solicitor.

Dr. BATEMAN also answered as representing the Medical Defence Union (the complainants), and replying to the PRESIDENT stated that he had witnesses in attendance, but he ventured to say that the case was one which he thought should be heard *in camerâ*.

The PRESIDENT: What do you say, Mr. Bodkin?

Mr. BODKIN: I have nothing to say. I cannot oppose it or assent to it because of the particular view I take of the case.

The PRESIDENT: You are neutral.

Mr. BODKIN: Entirely.

The PRESIDENT then put the question that the Council go into *camerâ* on the case.

There was no dissent expressed and strangers were accordingly asked to withdraw. They were not readmitted during the sitting, which was prolonged beyond the ordinary time of adjournment.

[illegible]

ar

wh

we

the

Thursday. The witnesses for the defence in attendance numbered about a dozen.

THURSDAY, MAY 28TH.

The Council resumed its sittings to-day, Sir WILLIAM TURNER, the President, being in the chair.

The Case of Dr. William George Niall.

The Council at once went again into *camerâ* on this case, but after a further consideration of it for an hour and a half decided to adjourn it till the November session.

The Case of Mr. D. B. Bradlaw.

The Council proceeded with the case of David Barnett Bradlaw, registered as of 4, Harrington-street, Dublin, Lic., Lic. Midwif. 1899, R. Coll. *Phys.* Irel., Lic., Lic. Midwif. 1899, R. Coll. Surg. Irel., who had been summoned to appear before the Council to answer the following charge, as formulated by the Council's *solicitor*:—

> That you, being a registered medical practitioner, have associated yourself in dental practice with your brother, Henry Jacob Bradlaw, a dental practitioner, registered as residing at No. 4, Harrington-street, Dublin, and have carried on a dental practice at No. 146, Inverness terrace, Bayswater, W., in your said brother's name, and

have personated him; and further, that the dental practice carried on at No. 146, Inverness-terrace, as aforesaid is extensively advertised by pamphlets and in newspapers and otherwise.

Mr. Bradlaw appeared to answer the charge, accompanied by Mr. A. Houston and Mr. L. H. Rosenthal, his counsel, instructed by Mr. Emanuel, his solicitor. Mr. R. W. Turner, instructed by Messrs. Bowman and Curtis-Hayward, attended in support of the case for the complainants, the British Dental Association. The Council's solicitor read the notice to attend.

Mr. TURNER explained that this case arose out of proceedings taken in the Marylebone police-court in March last. There were two brass plates on the door at 146, Inverness-terrace, one giving the name of the accused and the other that of his brother, the dental practitioner. Mr. D. B. Bradlaw, in the defence he had put in, stated that he had sublet part of his house and attended dental patients when his brother was absent in Ireland, but he did not tell them that he was either the medical or dental practitioner. As regards the advertising he had absolutely nothing to do with it. He was quite prepared to make his brother give up advertising or to take another address. He had not associated himself in trade with his brother and he had not done anything against the honour of his profession. He asked the Council to overlook his error of judgment.

The other statutory declarations were held as read.

Mr. HOUSTON did not dispute the facts and proceeded to address the Council. He said that Mr. Bradlaw was a man of very good reputation and had testimonials of the strongest from a number of the most eminent men in his own country. These testimonials showed that Mr. Bradlaw was a practised dentist and if they convicted him of the charge, it would be on the word of what he might call an inquiry agent and would disregard the testimonials from these eminent men who knew him. With respect to the advertising, the advertisements were perfectly harmless; and that the two practices were carried on in the same house could not detract anything from the character of the medical man from whose house the advertisements were issued. He denied personating his brother or associating with him in his business, but he was never asked in his brother's absence whether he was the brother or the other. He expressed his regret for anything done. He had stopped the advertising and also the dental practice. The brother, if he set up another practice, was not to be permitted to set it up at Inverness-terrace.

This closed the case and the Council deliberated in private. On the readmission of strangers,

The PRESIDENT, addressing Mr. Bradlaw, said: The Council has deliberated on your case and the conclusion it has come to is—that the facts alleged against you in the notice of inquiry have been proved to its satisfaction, but it is willing to give you an opportunity of satisfying it as to your conduct in the future, and it will adjourn further consideration till next session. You will then have to appear before the Council and satisfy it that your conduct in the interval has been quite satisfactory.

Mr. BRADLAW: Thank you.

The Case of Mr. E. A. Cloete Smith.

Consideration was next given to the case of Edward Arnold Cloete Smith, registered as of 1, Westbourne-street, W., Mem. R. Coll. Surg. Eng. 1884, Lic. R. Coll. Phys. Lond. 1884, who had been summoned to appear before the Council to answer the following charge, as formulated by the Council's solicitor:—

That you have systematically sought to attract practice and patients by means of circulars, circular letters, and inspired articles in the lay press, the circulars and circular letters printing your name, and in some cases your address, and publishing your name as surgeon of an institution which publicly advertises treatment of cancer by electricity, called the Free Hospital for Medical Treatment of Cancer by Electricity.

Mr. Cloete Smith appeared to answer the charge accompanied by Dr. Hugh Woods, Secretary of the London and Counties Medical Protection Society, of which he was a member, and Mr. J. W. H. Thompson, a solicitor, who attended as a witness.

Dr. BATEMAN attended on behalf of the Medical Defence Union, the complainants, and in opening the case, explained that the Free Hospital was at Notting Hill Gate and Mr. Cloete Smith was the physician in attendance. If Mr. Cloete Smith did not circulate the prints himself they were circulated for him, and he ventured to submit that the accused had been guilty of advertising for the purpose of procuring patients.

Mr. T. W. TYRRELL, clerk to Messrs. Hempson, went into the witness-box and confirmed a statutory declaration of his which was held as read.

In answer to Mr. Thompson he said that at the hospital he asked whether they accepted donations, and was told that they did. Asked if he saw anything in the hospital that was not in other hospitals he replied, certainly, for he saw two luxuriously furnished waiting rooms.

This closed the case for the complainants.

Mr. CLOETE SMITH asked the Council to allow Dr. Woods to conduct his case.

After some conversation Dr. Woods received permission to put questions.

Mr. J. W. H. THOMPSON, the solicitor accompanying Mr. Cloete Smith, in answer to Dr. WOODS, said that he and his wife had some money, and his wife wished to take some of it in research of treatment of cancer. The result of that was that they founded the hospital and asked Mr. Cloete Smith to act as physician of it. Mr. Cloete Smith was an old friend of his, and witness knew that for years he had been doing work in electricity. Witness was entirely responsible for the money. He took the house for two years as he was given to understand that nothing very satisfactory could be done in less than that time. It was a perfectly charitable institution: there was no element of profit in it. He never meant to make money from it and he asked no one for money. He had agreed to pay Mr. Cloete Smith 50 guineas, but that gentleman did not wish to take anything. Witness knew that probably he wanted a horse and he offered the money. Neither Mr. Cloete Smith nor anyone could make any profit out of the hospital, and witness was unaware of anything in the nature of advertising the hospital for Mr. Cloete Smith's advantage. With reference to a circular which was being issued by Mrs. Helen Black, a journalist, on one being handed to him he went to Mr. Cloete Smith's house and asked for an explanation. Mr. Cloete Smith assured him that he was not responsible for Mrs. Black's letters and that he had in no way inspired them. His reason for going to Mr. Cloete Smith was that when the hospital was founded no statements issued by witness appeared in the lay press. He considered the explanation satisfactory. On the Tuesda following Easter-day a pressman called on him. He said that a statement in regard to the treatment of cancer by electricity was to appear in his paper next day and he asked witness if he would give him some kind of statement in regard to his hospital. Witness told him that no statements in regard to medical matters should appear in the lay press and he refused to give information. He took exception to the way in which Mr. Tyrrell's declaration had been made and the evidence obtained. When the hospital was first opened a circular letter was sent to every hospital in London as it was desirable to let the officers of these institutions know of the existence of a new hospital. Anybody, of course, could have gone to the hospital at any time. The Medical Defence Union had let the matter go on from the beginning of April until now. He had received no intimation that it was considered objectionable. He heard of it only the other day and as it appeared to be rather peculiar he took exception to it.

Dr. BATEMAN: Mr. Thompson's position in connexion with this hospital is absolutely *bonâ-fide* and unassailable and I have no questions to ask him.

Replying to the President, witness said that he had drawn up the original letter relating to the founding of the hospital; he had done it for his wife.

In answer to Sir VICTOR HORSLEY, witness said that the hospital premises had, he believed, always been used as a private house. He was paying £160 per annum for the two years for it. He believed that everything had been done for the people who might come for treatment and the instruments and electricity appliances were second to none in London.

By Mr. BROWN: He found the entire expenses. As to one room being furnished better than another no distinction was made between people who came for treatment.

Mr. BROWN: Were there any means taken to exclude those who might be excluded.

The Witness: My wife personally sees the women applicants for admission and decides whether they are fit to be patients. The male applicants are looked after by my wife's secretary, who is an old schoolmaster, and he sees them all.

This having concluded Mr. Thompson's examination the further hearing was put off till Friday.

The English Conjoint Board's Report.

Sir VICTOR HORSLEY asked how it was that the report of the chairman of the Examination Committee on the question of the English Conjoint Board's primary examinations was not yet forthcoming. They had been promised that it would be in their hands on the morning of that day.

The PRESIDENT: No doubt you will get it to-morrow morning.

Sir VICTOR HORSLEY: But I am entitled to an answer to my question.

Mr. BRYANT: *I think you have got a satisfactory answer.* The report will be in the hands of the Council to-morrow.

Sir VICTOR HORSLEY: It is quite hopeless to expect to get a straight answer to a straight question from the chairman of the Examination Committee.

The Council adjourned.

FRIDAY, MAY 29TH.

The Council resumed to-day, Sir WILLIAM TURNER being in the chair.

The Case of Mr. Cloete Smith.

Proceedings in this case were continued, the parties appearing as before.

Mrs. HELEN BLACK, journalist, in answer to Dr. Woods, said that for years she had taken a great interest in the medical work connected with hospitals and had paid special attention to the recent discussions on the treatment of cancer. Some little time ago, about the end of February, she had written an article on the advantages of electricity in the treatment of cancer. That was done by her as a journalist. It was her own work and her own doing. It was published in the *Pall Mall Gazette*, but Mr. Cloete Smith had certainly not consulted with her before the article was published. She had had no interview with him on the subject and he knew nothing whatever about it. With reference to the so-called private letters or circulars sent out by her respecting the hospital in question, these had been sent out in reply to requests for information, sent out as private letters to her friends. She had got prints in order to avoid the trouble of writing. She had not mentioned *the circular she was about to send out before she got copies* printed. She had sent Mr. Cloete Smith a copy and on receiving it he had asked her to stop the issuing of them. She had no idea whatever that they were, or would be regarded as, advertisements. They were simply private answers wished by friends.

Cross-examined by Dr. BATEMAN: She had had several conversations—not what might be called interviews—with Mr. Cloete Smith. She had been told that his information and ability might be of advantage to her in connexion with a hospital at Southampton and she wanted to find out, but he had never asked her to advertise the Free Cancer Hospital. He had never asked her to bring before the public any facts about it and she had published the article in the *Pall Mall Gazette* without his knowledge or consent. She had 2000 copies of the circular printed but only about 350 had gone out.

In answer to questions by members of the Council she emphatically denied that the newspaper article in question was an inspired production. In any conversation she had with Mr. Cloete Smith no suggestion was made that the facts might be brought before the public that a small hospital was to be opened for the treatment of cancer. The conversation was general.

Mr. CLOETE SMITH then gave evidence. In examination by Dr. WOODS he said that he had *no knowledge* whatever of the printed circular which Mrs. Black issued before it was sent out by her and as soon as he heard of it he telegraphed to the lady to stop the issue. He had absolutely no knowledge whatever of, and was not associated in any way with, the article Mrs. Black had published in the *Pall Mall Gazette*. It was days after it appeared before he saw it. He had been a serious student of electricity for a considerable number of years and an article of the nature of that in question would not, in his opinion, redound to anyone's credit. He admitted having had conversations with Mrs. Black, but in these he had no idea that she was going to publish anything he had said. Asked if he was deriving any profit from his connexion with the hospital, he replied that he was working at a dead loss.

Cross-examined by Dr. BATEMAN: Is there anything done in the way of electrical treatment in this small hospital that is not done at every London hospital?—I fancy that the method is a little different. It may be more prolonged, there may be certain details in the treatment and in the instruments, and in these details there may be difference.

In answer to the PRESIDENT, witness said that the institution was not to be regarded as a home and it was not an in-patient hospital at all. It was to offer the advantage of special treatment.

After some further questions the evidence was concluded and Mr. CLOETE SMITH addressed the Council in defence of himself. The Council deliberated in private. On re-admission of the parties

The PRESIDENT, addressing Mr. Cloete Smith, said: The Council has decided that the facts alleged against you in the notice of inquiry have not been proved to its satisfaction.

University Representation on the Council.

The Council resumed consideration of the following motion by Mr. JACKSON, adjourned from Saturday last:—

> That the C[illegible] Council that in the event of the [illegible] ito two or more separate univer-[illegible] continue to represent the whole collectively.

[illegible] He thought that it would b[illegible] the Council to give any ac[illegible]ould have the effect of raising against them the opinion of the people of Lancashire and Yorkshire, who were subscribing large sums of money for the purposes of higher education. He held that the younger colleges of Manchester, Liverpool, and Leeds would be all the better for being represented on the Council by themselves and if they were to propose to give to each of these colleges only one-third of a member, it would, in the opinion of the people of these localities, mean that these institutions were to be put on a lower level than the universities elsewhere, some of which were not as large as the Owens College, Manchester. The new question of having an extra chair or two in that room was neither here nor there. Suppose the Council were to pass this motion and to send it up to the Privy Council they might be told that they were exceeding their duty. Did they suppose that any Government would encounter the opposition of such an influential body of opinion as the people of Lancashire and Yorkshire? He hoped that the Council would decide against the motion by a large majority.

Sir C. NIXON said that it was not the business of the Council when a new university had been created by charter to volunteer its advice to the Government that the privileges of that university should be withheld from it. He sincerely hoped that the Council by an overwhelming majority would decide against the motion.

Sir VICTOR HORSLEY appealed to Mr. Jackson to withdraw his motion. He could not vote on the question one way or the other until he had seen the terms of the charter of the Victoria University. It might turn out that the university were not claiming representation and he should like to see the charter first.

Dr. BENNETT moved the "previous question."

Dr. ATTHILL seconded this amendment.

On a show of hands the "previous question" was carried and the motion accordingly dropped.

Examinations of the Apothecaries' Hall, Dublin.

The Council resumed consideration of the following motion by Dr. MACALISTER:—

> [illegible]

Mr. TICHBORNE now produced certain documents in connexion with the case. He said he did not think that there had been any great harm done, because the gentleman in question passed almost with honours; he got very high marks in two of the subjects and passed very well in the third.

The motion was agreed to.

A Special Session in July.

The next business on the agenda was "to receive a report from the Education Committee" and the following notice of motion by Mr. BRYANT:—

> That the consideration by the Council of the Inspectors' and visitors' reports, and of the report on these by the Examination Committee, be postponed until July 28th, when a special meeting of Council shall be held for the purpose of taking them into consideration.

The PRESIDENT said that they had got rid of their penal business, which had cost them a great deal of money, and he did not know that the result was altogether worth the money. But still they had gone through the most laborious and to many of them the most disagreeable task. Now they came to that part of their business which constituted in his judgment the most important part—namely, the question as to the education which a person was to receive and the examination through which he was to pass before he was admitted to the Medical Register. There was before the Council a large mass of important material to consider and first on the programme was "to receive a report from the Education Committee." Then came a motion by Mr. Bryant to postpone the consideration of the reports by the Examination Committee on the inspectors' and visitors' reports. Next followed reports by the Examination Committee on the inspection of final examinations and after that came reports by the same committee on the inspection of certain primary examinations It was obvious from the notice of motion by Mr. Bryant that the question was going to be raised whether these reports of the Examination Committee should be considered at this session or postponed till a later date. He understood that the report of the Education Committee was intimately linked with the reports of the Examination Committee on the inspection of primary examinations, and the question arose in his mind if there was to be a postponement of the reports of the Examination Committee, should there not also be a postponement of the report of the Education Committee? But he would point out to members of the Council that if this postponement did take place it meant a considerable expense.

Mr. TOMES: Can you tell us what the probable expense will be?

The PRESIDENT: It depends on the number of days the Council sits. It is something between £150 and £200 a day; that you may take as a fair average.

Mr. ALLEN (Registrar): £650 for a session of two days and £175 for each following day.

The PRESIDENT: What a very expensive body the Council is!

Mr. BROWN suggested that the inspectors' and visitors' reports should be received and entered on the minutes.

The PRESIDENT said he would agree to that on one condition, that the motion to receive the reports was accepted without debate.

Dr. MCVAIL objected to the reports being entered on the minutes until the Council was going to discuss them. It would be quite unfair to the representatives of the bodies concerned who should have an opportunity of making a reply.

Mr. BRYANT then formally moved the proposal standing in his name:—

> That the consideration by the Council of the inspectors' and visitors' reports, and of the reports on these by the Examination Committee, be postponed until July 28th, when a special meeting of Council shall be held for the purpose of taking them into consideration.

He said he merely brought forward the motion as the mouthpiece of the committee but his own opinion was the other way.

Dr. MCVAIL, in seconding the motion, said that it was the unanimous finding of the committee with the exception of Mr. Bryant who expressed an opinion neither way.

Sir WILLIAM THOMSON said he was not in favour of the motion and he was a member of the Examination Committee.

Dr. MCVAIL said the Examination Committee had sat that week 12½ hours and it was, perhaps, the most arduous work the members of the committee had ever been engaged in. Very full consideration was given by the committee to every one of the reports and the serious question which the members of the committee had to consider was whether they should agree or disagree with the opinions expressed in these reports. What the committee felt was this: could the members of the Council do justice to these reports without having them in their hands for consideration for two or three weeks? The Council had taken four and a half days for the penal work. Were they to grudge the money necessary for carrying on what was really the most important business of the Council? If it was right that they should postpone the reports the question of expense should not stand in the way. He understood there were certain important members of the Council, including the President, who could not be there after Saturday and he was sure they would all agree with him that to consider these important reports without the President would be wrong.

Sir WILLIAM THOMSON opposed the motion. It would be very inconvenient to many members of the Council to return to London in July for a special session. The matters dealt with in the reports of the Examination and Education Committees were very important to the colleges and conjoint bodies concerned and it was an exceedingly unpleasant thing for these bodies to have the reports talked about and the effect of them leaking out. He thought it would be much better that the Council should come face to face with these bodies without further delay. They had been dangling over the business for five or six years and at last when they had got to a definite point they were met by a motion for postponement until next July or November. He submitted that as the Council was now in session it would be far better to go on for two or three days longer rather than face again the great inconvenience of a special session in two months' time.

Dr. WINDLE said he should have preferred to go on with the work but the President had intimated that it was impossible for him to be present after Saturday. This was a matter of such great importance that the Council ought to have the President in the chair when it was being discussed. That was his sole objection to proceeding with the business this session, but he hoped the Council would meet at the earliest possible date. This matter had been hanging in the air for nearly 12 months. All sorts of remarks had been made about it in the medical journals and it was not fair that that sort of thing should be carried on for another six months.

Sir C. NIXON and Dr. NORMAN MOORE supported the motion for postponement.

Dr. PYE-SMITH protested against the proposal to have a special meeting for the consideration of the reports. He should have thought that the state of their finances was quite sufficient to show how unjustifiable was the motion. The expense ought to be seriously considered. He held that the Council had no right to spend what, after all, was other people's money. They had spent at the present meeting an enormous sum of money with small fruits. There was nothing very urgent in the reports of the Examination Committee and they could quite well be postponed for a little longer. A special session in July would probably end in a fiasco, as was the case on a former occasion when a special meeting of the Council was held. He moved as an amendment that the reports be postponed till the next ordinary session in November.

Dr. LITTLE seconded this amendment.

Dr. MCVAIL hoped the Council would not agree to the amendment. The representatives of the bodies concerned should have the right of discussing the reports and the observations of the committee upon them at the earliest moment, if they desired it. It was entirely in consideration of their position that he seconded Mr. Bryant's motion for a postponement to an early date. He totally differed from Dr. Pye-Smith in describing a previous special meeting of the Council as a "fiasco" and said that that style of argument was not likely to insure that members of the committees would devote such earnest and close attention to the matters that came before them as had hitherto been the case.

Dr. BRUCE said that to have a special meeting within three months of the ordinary session in November was, on the face of it, acting the part of spendthrifts. He believed that no harm would follow from the postponement till November. The difficulty of settling any date for a special meeting would be very great. Whatever date was fixed it might not be convenient for some members.

Dr. FINLAY suggested that Mr. Bryant should withdraw his motion.

Sir VICTOR HORSLEY hoped that the Council would not be guided by the question of expense in deciding whether there should be a special meeting. They would have a full programme in November and to postpone all this mass of material till then would greatly overload the next ordinary session. The mere question of travelling expenses was a small item compared with the important work which the Council had got to do. He therefore hoped the Council would agree to have a meeting some time in July.

Dr. PAYNE said that he should not be sorry if the matter was delayed till November. The body which he represented was not at all anxious to bring the matter to a crisis.

Mr. BROWN suggested that the Council should adjourn that evening and meet again on June 3rd or 4th.

On a show of hands Dr. Pye-Smith's amendment to postpone consideration of the reports till the ordinary session in November was rejected by 13 votes to 11.

Mr. BRYANT informed the Council that the reports of the Examination Committee on the inspection of the final examinations of the Universities of Cambridge, Durham, and Victoria were ready and could be dealt with by the Council before the adjournment.

On the motion of Dr. MACALISTER, Mr. Bryant's motion was then amended by omitting the date "July 28th" and adding the words "other than the reports of the Cambridge, Durham, and Victoria Universities."

A good deal of discussion ensued as to the most convenient date for the special session. Various dates in July were mentioned.

Dr. NORMAN MOORE proposed and Dr. BRUCE seconded that the next ordinary session should be held on Oct. 26th, but this did not find much favour among the members and it was stoutly opposed by Dr. MCVAIL who denounced the proposal as a "manœuvre" on the part of those who objected to any special meeting.

It was ultimately decided that the special meeting should be held on July 15th and Mr. Bryant's motion was carried with the insertion of this date.

It was further resolved to postpone the consideration of the report of the Education Committee to the same special meeting.

Final Examinations.

Dr. MACALISTER thought that though consideration was postponed it would be advisable at once to place on the minutes the reports from the Examination Committee on the inspection of the final examination of the Universities of Durham, Victoria, and Cambridge and also those respecting the Universities of London and Oxford and the Conjoint Board in England.

Sir VICTOR HORSLEY supported this view and the Council agreed.

Extracts from these reports follow :—

CAMBRIDGE UNIVERSITY.

There is no examination in forensic medicine, nor examiners. There was only one question set in hygiene and there was no oral or practical examination in that subject, or any special examiner. The examination in surgery was pronounced by the inspector to be excellent The surgical examination was upon the whole a very thorough one and possessed some features which are well worthy of close consideration. The examination in midwifery and diseases of women is described by

Concerning chemistry and physics the committee agrees with the visitors that "the standard is a low one"; and that "the main portion of the practical examination is empirical and not scientific, and is no test either of sound principles or of practical efficiency."

Returns from Teaching Institutions.

On the motion of Sir Victor Horsley, seconded by Sir John Batty Tuke, there was also formally received and entered on the minutes a report by the Education Committee on the returns supplied by the Examining Board in England pursuant to a request made by the General Medical Council in a resolution passed on Feb. 26th, 1902, showing the answers given by the teaching institutions recognised by the Royal Colleges of Physicians and Surgeons in London, but not approved by the General Medical Council, regarding the courses of study in chemistry, physics, and biology to be gone through by candidates for the qualifications L.R.C.P. Lond. and M.R.C.S. Eng., with remarks by the Education Committee. These remarks were summarised in the following way:—

> From the statistics presented to and analysed by the committee two important facts emerge which the committee think worthy of special emphasis:—
>
> I. The Royal Colleges of England do not demand, as an essential for admission to their professional examination in chemistry, physics, and biology, that any certified course of instruction in these subjects should be taken subsequent to the preliminary examination in general knowledge. It is understood that at some period the student has studied these subjects in a recognised school, but he may present himself for examination in them immediately after passing the preliminary examination, and the licensing body relies, for evidence of his knowledge, solely upon the results of its own examination.
>
> II. In cases where the whole time spent upon these three subjects is antecedent to the date of the preliminary examination in general knowledge the licensing body does not permit the prescribed five years' curriculum in medical study to be curtailed thereby. All students are required subsequent to the preliminary examination to devote five years to medical study. But on the other hand a student whose course of study in chemistry, physics, and biology is taken out subsequent to the date of his preliminary examination is permitted to count, as part of the necessary five years, any period from three months to one year spent in one of the recognised schools, provided that during the period specified—three, six, or nine months, as the case may be—he engages in study in one, two, or all of, the subjects mentioned. In the majority of the recognised institutions biology is not taught and as a consequence the student who spends a portion of his first year of medical study in one of these schools in most instances confines his professional work to chemistry and physics and very frequently takes these subjects in conjunction with others which form part of the ordinary school curriculum. In most of the schools the course of instruction followed in chemistry and physics is less than 15 hours a week; in many it is very much less. And it is evident from the statistics presented that in some of the cases it is actually possible for six months of medical study to be constituted by a course of instruction in chemistry and physics, limited so far as these subjects are concerned to four or five hours a week and taken out at an ordinary grammar school during school hours, or at a technical institute, it may be in its evening classes.
>
> *Note by Dr. Norman Moore on the returns:*—It should be observed that the principle generally adopted in the recognition of institutions by the Conjoint Board has been that where the laboratories and appliances are satisfactory and the teachers efficient, the syllabus and examination of the Board will, in chemistry, physics, and biology, be sufficient to regulate the course of study.

The Pharmacopœia.

At the request of Dr. MacAlister, who said that he had nothing to add, the following report was received and entered on the minutes:—

> The Pharmacopœia Committee beg leave to report that up to the present date 33,880 copies of the British Pharmacopœia, 1898, and 541 copies of the Indian and Colonial Addendum, 1900, have been disposed of.
>
> As the issue of 1500 copies of the Pharmacopœia ordered by the President in July of last year was nearly exhausted by the end of March it became necessary to direct the printers to prepare a further supply. On inquiry it appeared that an appreciable saving would be effected if a larger issue than 1500 were printed and the President accordingly, after consultation with the chairman of the committee, gave orders for an issue of 3000 copies. This supply should, at the present rate of sale, suffice for two years or more. The committee recommend that the action taken in the matter be approved by the Council.
>
> The committee have received an interim report on the Pharmacopœial tests for arsenium from Professor W. R. Dunstan, F.R.S., who has undertaken to investigate for the committee certain important questions bearing on this subject. The investigations are being made under Professor Dunstan's direction in the laboratories of the Imperial Institute. As the inquiry involves a large amount of laborious work the committee propose, with the approval of the Council, to make a grant towards the necessary expense involved.
>
> The first instalment of a digest of criticisms and researches bearing on the revision of the Pharmacopœia, prepared for the committee by Mr. William Chattaway of the Society of Apothecaries, has just been received and the remainder will be ready in a short time. This digest will be of great service in suggesting the directions in which further investigation may be necessary before the preparation of the next Pharmacopœia is undertaken.
>
> Notice has been received of the resignation of Mr. Charles Ekin, who, with Dr. W. Inglis Clark, has since 1899 represented the Pharmaceutical Society of Great Britain in the conference with members of the committee which was sanctioned by the Council on Nov. 30th, 1898. The committee desire to record their thanks to Mr. Ekin for his services in this connexion.
>
> Gifts of books and pamphlets for the library have been received from Professor H. C. Wood, Dr. Payne, Dr. Power, and the chairman.

Dr. MacAlister, in answer to Mr. Brown, said that in respect to Dr. Inglis Clark the matter rested with the Pharmaceutical Society.

Mr. Brown: I should like to propose that it is not necessary that the vacancy should be filled. I have reasons for that.

Dr. MacAlister: I think you should leave the Pharmaceutical Society to mind its own business.

Application for Registration.

A report was submitted from the English Branch Council recommending that an application for registration by Mr. William Bennett Rule, Mem. R. Coll. Surg. Eng., 1866, Lic. R. Coll. Phys. Edin., 1867, a medical practitioner entitled to be registered under the Medical Act (1858), but who neglected to effect such registration until after the "appointed day" (June 30th, 1887), under the Medical Act (1886) should be granted.

On the motion of Dr. MacAlister, seconded by Mr. Bryant, the recommendation was adopted and the Registrar was directed to place Mr. Rule's name upon the Medical Register.

Committees of Council.

Committees as follows were appointed:—

Pharmacopœia Committee.—Dr. Norman Moore, Sir George Philipson, Dr. Payne, Dr. MacAlister, Sir John Tuke, Dr. McVail, Dr. Atthill, and Mr. Tichborne.

Finance Committee.—Dr. Pye-Smith, Mr. Bryant, Dr. Heron Watson, Dr. Bennett, and Mr. Tomes.

Dental Committee.—The President (Chairman), Mr. Bryant, Dr. Heron Watson, Mr. Tomes, and Sir Charles Ball.

Dental Education and Examination Committee.—Mr. Bryant, Mr. Brown, Mr. Tomes, Dr. Finlay, Sir Charles Ball, Dr. Lindsay Steven, and Dr. Bennett.

Students' Registration Committee.—Sir Hugh Beevor, Dr. MacAlister, Sir John Tuke, Dr. Mackay, Dr. Bennett, and Sir William Thomson.

Examination Committee.—Nominated by the English Branch Council: Mr. Bryant, Mr. Young, and Dr. Payne; by the Scottish Branch Council: Dr. Heron Watson, Dr. McVail, and Dr. Finlay; and by the Irish Branch Council: Sir Charles Ball, Dr. Little, and Sir William Thomson.

Education Committee.—Nominated by the English Branch Council: Dr. Norman Moore, Dr. MacAlister, and Dr. Windle; by the Scottish Branch Council: Sir John Tuke, Dr. Mackay, and Dr. McCall Anderson; and by the Irish Branch Council: Sir C. Nixon, Dr. Bennett, and Sir William Thomson.

Public Health Committee.—Nominated by the English Branch Council: Mr. Power, Mr. Jackson, and Sir G. Philipson; by the Scottish Branch Council: Dr. Bruce, Dr. McVail, and Dr. Lindsay Steven; and by the Irish Branch Council: Sir Charles Ball, Mr. Tichborne, and Dr. Bennett.

Public Health Committee.

On the motion of Dr. Bruce, seconded by Sir Charles Ball, a report from the Public Health Committee, from which the following are extracts, was received and entered on the minutes:—

> 1. The committee considered a communication from the Director-General of the Army Medical Department giving particulars of the proposed military sanitary districts, with their approximate populations. After due consideration, the committee agreed to recommend the Council to recognise on the present occasion the following districts, viz.:—Aldershot, Salisbury Plain, Southern and Western Districts, Dublin and Cork Districts; [illegible], [illegible] and Eastern Districts; North-Eastern and North-Western Districts, Scottish District, and Gibraltar, as meeting the requirements of the Council in accordance with Rule 3.
>
> 2. The committee had submitted to them a letter dated 16th May, 1903, from the Clerk of the Metropolitan Asylums Board, inclosing a resolution of that body in regard to the attendance at fever hospitals of candidates for diplomas in public health in accordance with Rule 4. The committee consider that this scheme meets in the fullest manner the rules and requirements of the Council for diplomas in public health. The committee suggest that the Council should express gratification that the Metropolitan [illegible] Board has seen its way to afford to students preparing for [illegible] such ample opportunities for complying with [illegible].

It was agreed to adopt Part 1 and that the military districts there recommended be the recognised military sanitary districts.

In moving the adoption of Part 2, Dr. BRUCE said that the Clerk to the Metropolitan Asylums Board was very anxious to meet the wishes of the Council in this matter. He had given every opportunity to secure inspection of diseases and if the Council approved of this report he thought they should express their thanks to the Metropolitan Asylums Board for allowing such opportunities as it was giving for the study of sanitary science.

Dr. NORMAN MOORE seconded the proposal which was agreed to.

The PRESIDENT: We shall see that a letter is duly sent to the Board.

The Council adjourned.

WE have received a letter from Mr. Henry Varley complaining of our publication of the reference made at the General Medical Council to certain pamphlets written by him and addressed to young men. We made no comment on the proceedings, but, although we do not impute improper motives to Mr. Varley, we must say, having read his pamphlets, that they are not fitting works to be retailed to anyone who likes to buy them for 6*d*. or 3*d*.—ED. L.

Medical News.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the first professional examination for the Fellowship at the half-yearly meeting of the examiners in May:—

[illegible] Hospital; James Vere Arkle, M.R.C.S. [illegible] aland University, and St. Thomas's [illegible] University [illegible] Rowland Alessandro Bowling, [illegible] hn Davis Barris, B.A. Camb., [illegible] College, London; Albert Ogi [illegible] London Hospital; Laurence [illegible] Thomas Charles Clare and Joseph Bernard Dawson, Birmingham University; George Coates, M.D. Glas., Glasgow University and King's College, London; James Douglas Cooke, M.B., B.S. Melb., Melbourne University and London Hospital; Vincent Zachary Cope, St. Mary's Hospital; Claude Harold Cross and Reginald Cheyne Elmslie, M.B., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's Hospital; John Dundon, M.B. R.U. Irel., F.R.C.S. Irel., Queen's College, Cork; Watts Edmondson, Yorkshire [illegible] Mungo's College, [illegible] R.U.I., Queen's [illegible] thelbert Rest Flin [illegible] e, Manchester; [illegible] Lond., London I [illegible] French, [illegible] London [illegible] iversity [illegible] Lond., [illegible] Hussey [illegible] ondon; [illegible] Toronto [illegible] M.A., [illegible] ty and St Bartholomew's Hospital; Frederic William Forbes Ross, M.D., C.M. Ed., M.R.C.S. Eng., L.R.C.P. Lond., Edinburgh University and University College, London; Cecil William Rowntree, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., Middlesex Hospital; Wallace Arthur Scott, M.B. Toronto, M.R.C.S. Eng., L.R.C.P. Lond., Toronto University, University and King's Colleges, London; George Stanley Thompson, St Mary's Hospital; Charles Ferrier Walters, M.R.C.S. Eng., L.R.C.P. Lond., University College, Bristol, and King's College, London; Albert James Walton, London Hospital; and Philip Roscoe Wrigley, M.R.C.S. Eng., L.R.C.P. Lond., Owens College, Manchester.

123 gentlemen presented themselves for this examination, of whom 40 passed and 79 were referred.

UNIVERSITY OF CAMBRIDGE.—The following medical degrees were conferred on May 28th:—

Doctor of Medicine.—S. H. Long, Gonville and Caius.

Bachelor of Medicine and Bachelor of Surgery.—J. McBryde, King's; F. H. Pearce, Trinity; W. H. Bradley, Queen's; H. T. Thompson, Christ's; and G. W. Greene, Downing.

Bachelor of Medicine.—H. W. Atkinson and R. F. Williams, Gonville and Caius.

Bachelor of Surgery.—F. S. Kidd and J. E. Spicer, Trinity; J. E. Frere, Pembroke; H. Statham, Christ's; and W. B. Crowfoot, Emmanuel.

The graces for the re-establishment of the professorship of surgery will come before the Senate on June 11th.

ROYAL BRITISH NURSES' ASSOCIATION.—Her Royal Highness Princess Christian will preside at the annual [illegible] Association to be held [illegible] June 6th, at 3 30 P.M.

TENBY.—A large section of the British Medical Association will this year visit the town of Tenby in Pembrokeshire. We are asked to mention the fact that an illustrated souvenir of the town can be obtained gratis and post free upon application to the Secretary of the Improvement Association, Tenby. The guide contains nearly 50 full-page photographic pictures of Tenby and its environs, whilst the descriptive matter is contributed by Dr. D. A. Reid, the borough medical officer of health.

MEDICAL GOLF TOURNAMENT.—The sixth annual tournament was held on May 28th on the links of the Hanger Hill Golf Club, to which club thanks are due for its courteous hospitality. There was a large entry in both [illegible] down to bogey; second prize, tied for at three down by Dr. Vassie and Dr. Maclaren; best last nine holes, Dr. James Taylor with the good score of two up. Second class: Resulted in a tie at four down between Dr. Gordon Watson, Dr. Alderson, and Dr. Schofield; best last nine holes, Dr. Schofield with all square. A keenly contested foursome competition *v.* bogey was won by Dr. Seymour Taylor and Dr. Lyle with the fine score of two down.

CHELSEA CLINICAL SOCIETY.—Dr. C. C. Gibbes, the President of the society, took the chair at the annual dinner of the society, which was held at the Holborn Restaurant on May 26th. In the course of proposing the toast of "The Chelsea Clinical Society" the President traced the origin and rise of the society and congratulated the members on the continued success of their annual debates. He ascribed the satisfactory condition of the society to the fact that what he called subjects of a "high falutin'" character were severely left to be dealt with by the societies which assembled at 20, Hanover-square, and which favoured topics of a high and mighty, but extremely dry, kind. The members of the Chelsea Clinical Society were ordinary mortals and supported their society because it not only afforded them help by means of the papers read at their meetings, but it also enabled them to make a *determined stand against any encroachment* on their rights.—Dr. T. V. Dickinson, the president-elect, responded to the toast, which was followed by that of "Kindred Societies," proposed by Dr. W. Ewart and replied to by Dr. W. Hale White and Dr. G. Herschell. The toast of "The Visitors" was intrusted to Mr J. F. Palmer and acknowledged by Dr. Hector W. G. Mackenzie and Dr. T. B. Hyslop.—Mr. C. A. Morris proposed "The President" and Mr. Noble Smith "The Officers of the Society," to which the officers concerned responded.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, MAY 28TH.

The Infected Blankets.

[illegible] State for War whether, in [illegible] eak of fever [illegible] s, he would [illegible] the officers [illegible] the medical [illegible] all not be in [illegible] ect of the [illegible] though the health committee of the city took steps to prevent the further distribution of these blankets, some portions of the consignments in question had already been sold and distributed to villages in the neighbourhood; and, if so, whether he would state what steps he was taking in the matter.—Mr. Long: I have communicated with the town clerk of Nottingham on the subject, who has informed me this morning that, in consequence of the action taken by the medical officer of health in notifying the persons in the villages referred to who had purchased the blankets, the whole of these articles have been sent back to the firm at Nottingham who supplied them. The town clerk adds that all the blankets which reached Nottingham, some hundreds in number, are in process of disinfection.

Outbreak of Ophthalmia.

Mr. Herbert Samuel asked the President of the Local Government Board whether he was aware that an outbreak of ophthalmia at the Hanwell Poor-law schools had affected 230 children between April 4th and May 16th of this year; whethe [illegible] that this outbreak had been due to [illegible] from the ophthalmic school to th [illegible] he would state what steps had been taken in the matter.—Mr. Long: I am aware of the outbreak which has recently occurred at the schools referred to. The managers obtained the services of Mr. Sydney Stephenson and I have seen a report by him on the subject. It appears that the outbreak was a mild form of conjunctivitis or "blight." This is an ailment which is very prevalent among children and which readily yields to suitable treatment. I am not aware of any report to show that the outbreak was due to the cause referred to in the question. Indeed, the evidence indicates that the infection was introduced into the schools by a child recently admitted from Southwark. I am informed that the managers re-opened a portion of the former ophthalmic school for the reception of the children affected, and I understand that the action which they have taken on the advice of Mr. Stephenson is being attended with success. Only 60 of the children now remain isolated and under treatment.

Epidemics in a Poor-law School.

Mr. Herbert Samuel asked the President of the Local Government Board during how many weeks in the past 12 months there had been epidemics of illness in the Hanwell Poor-law schools.—Mr. Long It appears from a return which I have received from the clerk to the managers that during the year ended Saturday last there have been three slight epidemics of illness at these schools. Thus, there were 59 cases of influenza during nine weeks, 43 cases of chicken-pox during 12 weeks, and 26 cases of whooping-cough during 10 weeks. The total number of cases of all other diseases for the year is nine. During 13 weeks there was no case of disease in the schools. I am informed that there have been no deaths there since June, 1901. This reply does not take account of the mild attack of "blight" which had recently occurred in the schools.

Poor-law Nursing.

Mr. Talbot asked the President of the Local Government Board whether he had taken into consideration the Report of the departmental committee on Poor-law Nursing, dated Nov. 10th, 1902, and whether it was still his intention to recommend the training of a class of qualified nurses in the smaller workhouses.—Mr. Long: I can only state at present that the report referred to is under my consideration.

Royal Army Medical Corps.

Dr. E. C. Thompson asked the Secretary of State for India if he would explain why certain increases of pay and charge pay, granted by Royal warrant of March 26th, 1902, to officers of the Royal Army Medical Corps, and drawn all over the world since that date, were still withheld in India.—Lord George Hamilton: The Royal warrant of March 24th, 1902, amended certain articles of the pay warrant and was therefore subject to the last clause in the preamble of the pay warrant which declares that it is not in force in the Indian empire. The question of the pay of the Royal Army Medical Corps in India has however, been under consideration, and revised rates, giving a substantial increase to the ranks of lieutenant, captain, and lieutenant-colonel, have been sanctioned with effect from Nov. 24th, 1902.

Plague in the Punjab.

Mr. Weir asked the Secretary of State for India if he would state the number of persons who had died from plague in the Punjab since Jan. 1st last, and what percentage of these persons were inoculated with plague serum.—Lord George Hamilton: The number of persons who have died from plague in the Punjab, the population of which is 22½ millions, between Jan. 1st, 1903, and May 2nd (the latest date for which figures have been received) is 141,789. The returns do not distinguish deaths of inoculated persons from deaths of persons not inoculated.

Plague at Hong-Kong.

Mr. Weir asked the Secretary of State for the Colonies whether the system of inoculation with plague serum which was in force in India had been adopted in Hong-Kong and, if not, whether he would consider the expediency of calling for a report on the subject.—Mr. Chamberlain: The honourable Member will see from Dr. Simpson's report which has just been placed in the library of the House that the inoculation of those who wish to be protected with Haffkine's plague prophylactic is already carried on in Hong-Kong, and that Dr. Simpson recommends the continuance of this practice.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Adams, J. E., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

Badcock, C. H., B.A. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to Salisbury Infirmary.

Bevan, A., M.B. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Clinical Assistant in the Ear Department at St. Thomas's Hospital.

Biddle, Henry G., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer and Public Vaccinator for the St. Peter's District of the Isle of Thanet Union. (Corrected notice.)

Boycott, A. E., M.B., B.Ch. Oxon., has been appointed House Physician to St. Thomas's Hospital.

Bradford, A. B., M.B., B.S. Durh., has been appointed House Surgeon to St. Thomas's Hospital.

Carpmael, N., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

Coates, J., L.R.C.P. Lond., M.R.C.S., has been appointed Clinical Assistant in the Throat Department at St. Thomas's Hospital.

Colman, Frank, L.D.S., has been appointed Dental Surgeon to the East London Hospital for Children.

Dick, G. W., L.R.C.P., L.R.C.S., Edin., has been appointed Certifying Surgeon under the Factory Act for the Shotts District of the county of Lanark.

Edward, A. A., M.D. Edin., has been appointed Certifying Surgeon under the Factory Act for the Haslingden District of the county of Lancaster.

Glanville, W. M. G., M.B., B.Ch. Oxon., has been appointed Senior Obstetric House Physician to St. Thomas's Hospital.

Guthrie, T., L.R.C.P. Lond., M.R.C.S., has been appointed Clinical Assistant in the Skin Department at St. Thomas's Hospital.

Hedley, J. P., M.B., B.C. Cantab., has been appointed House Surgeon to St. Thomas's Hospital.

Henderson, T. B., M.A., M.B. Oxon., has been appointed House Surgeon to St. Thomas's Hospital.

Hildesheim, O., M.B., B.Ch. Oxon., has been appointed House Physician to St. Thomas's Hospital.

Hutchinson, J. R., M.B., Ch.B. Vict., has been appointed Junior Resident Medical Officer to the Chorlton Union Workhouse Infirmary, Withington.

Ibbotson, W., L.R.C.P. Lond., M.R.C.S., has been appointed Clinical Assistant in the Skin Department at St. Thomas's Hospital.

Joy, C. H., M.D. Durh., has been appointed Certifying Surgeon under the Factory Act for the Tamworth District of the county of Staffs.

Leach, R. E. H., L.R.C.P. Lond., M.R.C.S., has been appointed Clinical Assistant in the Throat Department at St. Thomas's Hospital.

March, J. Ogdin, L.R.C.P. Lond., M.R.C.S., has been appointed to the Medical Charge of the troops in camp at Lechlade, Gloucestershire.

McGill, J. M., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory Act for the Annbank District of the county of Ayr.

Milestone, Evelyn Stone, L.R.C.P. & S. Edin., M.D. Brux., has been appointed by the Education Committee, Sheffield, as Medical Officer for examining women teachers and female candidates for pupil teacherships.

Panton, B. N., B.A. Cantab., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant House Physician to St. Thomas's Hospital.

Philip, A., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory Act for the Newport District of the county of Fife.

Reid, W. A., L.R.C.P. & S. Edin., has been appointed Junior House [illegible] and Wakefield General Dispensary.

Ro [illegible] been appointed House Surgeon to [illegible]

Ross, E. A., M.B. Cantab., has been appointed Clinical Assistant in the Ear Department at St. Thomas's Hospital.

Sears, C. N., L.R.C.P. Lond., M.R.C.S., has been appointed House Physician to St. Thomas's Hospital.

Sergeant, J. N., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant House Physician to St. Thomas's Hospital.

Sexton, H. W., L.R.C.P. Lond., M.R.C.S., has been appointed House Physician to St. Thomas's Hospital.

Spurrier, H., B.A. Cantab., L.R.C.P. Lond., M.R.C.S., has been appointed Junior Obstetric House Physician to St. Thomas's Hospital.

Upcott, H., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

Wheen, C., B.A. Oxo[illegible] has been appointed Assistant House [illegible]

Wood, W. W., M.B., [illegible] under the Factor[illegible] of Stirling.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Army Medical Service.—Examination of Candidates for not less than 30 Commissions in the Royal Army Medical Corps.

Bath, Royal United Hospital.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

Brecknock County and Borough Infirmary.—Resident House Surgeon, unmarried. Salary £100 per annum, with apartments, board, attendance, fire, and gas.

[illegible]

MARRIAGE.

WEATHERBE—THURGARLAND.—On the 3rd June, 1903, at the parish church, Rotherham, by the Rev. J. W. Goodall, vicar, Dr. Lewis Johnstone Weatherbe of Ivy Lodge, Masboro', Yorks, to Ethel Louise, second daughter of Mr. Godfrey J. Thurgarland of Rotherham.

DEATHS.

FORD.—On January 23rd, at 5, St. Leonard's road, Surbiton, Joseph Ford, M.R.C.S., L.S.A., late of Wedmore, Somerset, aged 74.

HAVILAND.—On May 30th, at his residence, Ridgemount, Frimley Green, after two and a half years' illness, most patiently borne, Alfred Haviland, M.R.C.S. Eng., aged 78. No flowers, by request.

SPRIGGE.—On May 30th, at 6, Prince of Wales terrace, W., aged 26, Mary Ada Beatrice, second daughter of the Hon. Charles Moss, [illegible] M.B., of [illegible]

WE[illegible] 12.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

MEDICAL LEGISLATION IN THE ABRAHAMIC ERA.

CONTROVERSIES regarding the origin, authorship, and date of the Mosaic code have prevailed for 100 years and have within the last few months been revived in an intense form in consequence of archæological discoveries made by M. de Morgan at Susa in the end of 1901 and beginning of 1902. Interest at present centres in the inscription contained on a pillar of black diorite about eight feet high and consisting chiefly of a code of laws made by a Babylonian monarch whose name is variously transliterated as Hammurabi or Khammurabi and whose date is assigned to about 2200 B.C. On the publication, in France, of a photographic reproduction and a translation biblical critics immediately called attention to remarkable similarities in the codes ascribed respectively to Hammurabi and to Moses, the latter of whom is usually considered to have been born between 1600 and 1550 B.C. The discussions growing out of this circumstance will no doubt continue to occupy scholars for many years, but we do not propose to do more than refer to the clauses affecting medical practitioners as quoted on pp. 45–47 of the version by Mr. C. H. W. Johns (The [illegible] Co. 1903. Pp. 88. Price 1s. 6d.) and in the *Deutsche Medicinische Wochenschrift* of May 21st. The code consists of 282 clauses, those relative to practitioners of human and veterinary surgery being numbered 215 to 225. Scales of fees are authorised for surgical operations both on man and on domestic animals and a terrible fate was in store for the operator in the event of the human patient either dying or losing an eye. Ophthalmic surgeons must have been greatly devoted to their art who were content to accept the alternatives of a fee of from two to ten silver shekels when an operation was successful or amputation of both their hands when it failed. The following version is taken from the translation by Mr. Johns. The German rendering given in the *Deutsche Medicinishe Wochenschrift* differs from it in a few quite unimportant particulars. For instance, in the German the words "gentleman" and "bronze" are not represented and the word which Mr. Johns has translated "sheep" appears as "ass" (Esel).

§ 215. If a doctor has treated a gentleman for a severe wound with a bronze lancet and has cured the man, or has opened an abscess of the eye for a gentleman with the bronze lancet and has cured the eye of the gentleman, he shall take ten shekels of silver.

§ 216. If he (the patient) be the son of a poor man, he shall take five shekels of silver.

§ 217. If he be a gentleman's servant, the master of the servant shall give two shekels of silver to the doctor.

[illegible] cut off his hands.

§ 219. If a doctor has treated the severe wound of a slave of a poor man with a bronze lancet and has caused his death he shall render slave for slave.

§ 220. If he has opened his abscess with a bronze lancet and has [illegible] silver to the doctor.

§ 222. If it is the son of a poor man, he shall give three shekels of silver.

§ 223. If a gentleman's servant, the master of the slave shall give two shekels of silver to the doctor.

§ 224. If a cow doctor or a sheep doctor has treated a cow or a sheep for a severe wound and cured it, the owner of the cow or sheep shall give one sixth of a shekel of silver to the docto as his fee.

§ 225. If he has treated a cow or a sheep for a severe wound and has caused it to die, he shall give a quarter of its price to the owner of the ox or sheep.

ANGIO NEUROTIC ERYTHEMA AND ITS SURGICAL TREATMENT BY NEURECTOMY.

IN the May number of the *Bulletin of the Johns Hopkins Hospital* Dr. Joseph C. Bloodgood has published an account of three cases of angio-neurotic disease, in one of which the condition was multiple and was relieved by division of the nerves over the distribution of which the area of erythema and œdema extended. The patient was a female, white, and 17 years of age. She came under Dr. Bloodgood's observation in July, 1900. Her illness began about eight months before that date with signs of an abscess at the root of the right upper bicuspid tooth. There were persistent pain and tenderness referred to the right gum and cheek, and after about six

ENTITLED

A FEW JOTTINGS IN PHYSIOLOGICAL MEDICINE.

Delivered before the British Balneological and Climatological Society on May 21st, 1903,

BY GEORGE OLIVER, M.D., F.R.C.P. LOND.

MR PRESIDENT AND GENTLEMEN,—One of the far-reaching branches of physiology which has of late years been pressed into the service of medicine is the study of blood pressure and of the distribution of the blood. I propose to-night to glance at a few sections of this interesting chapter of physiological medicine which have more particularly engaged my attention during the past year or two and which may be of interest to some of you as practitioners in balneology.

NORMAL BLOOD PRESSURE.

The first requisite for the clinical study of blood pressure is a knowledge of the normal blood pressure, for that is, of course, the standard to which clinical deviations should be referred. It is well recognised that in healthy subjects it is liable to very appreciable variations above and below a certain mean and *these extremes of normal fluctuation* should be familiar to the practitioner. They are due to such physiological conditions as the ingestion of food, exercise, and temperature. I have taken the opportunity afforded by the past winter's rest from clinical work to study afresh these normal fluctuations of the circulation and I will now sketch an outline of the results. It may appear to you to be somewhat of a reversion nowadays to re-examine some of the elementary facts in our studies of blood pressure, but I think you will agree with me that the best possible assurance we can have of advancing securely in a somewhat untrodden field like this is to retrace our steps occasionally and to re-test *the safety and soundness of the track. In so doing* we may verify or correct our position and, moreover, we may perchance pick up a few fragments of truth which before we passed by unheeded. For the most part the observations on the arterial pressure were made with the hæmodynamometer, but Hill and Barnard's sphygmometer and Gärtner's tonometer were likewise used.

I have elsewhere[1] shown how delicate readings of the arterial pressure may be read for physiological purposes by the blood-pressure gauge. A small artery (like the superficialis volæ) is selected and the pulsation of the indicator is gradually developed to its maximum degree by gently increasing the pressure on the water pad when the reading is made and then it is found that beyond this point the motion at once diminishes. With a little practice differences of even one or two cubic millimetres of mercury may be reliably read. I have found it useful to use rubber covers[2] *which can be placed over* the *pad so that the motion* of the radial pulsation can be limited to a similar minimum range. [illegible] the arterial pressure [illegible] prevents a secondary [illegible] pt to be produced in some cases when a high pressure is applied to the pad and which may lead an observer to think that the arterial pressure is higher than it is.

THE INFLUENCE OF DIGESTION ON THE CIRCULATION.

During the past winter I have been much interested in the effects which the ingestion of food produces on the circulation. I had previously worked on this subject and the *results of the observations then made,* and published in 1901, were confirmed; but this more thorough and more critical inquiry has revealed an extension of these results. It has shown that the ingestion of food initiates a most interesting series of circulatory events which recur with perfect regularity after every meal. The observations have proved that the influence exerted by the act of digestion on the circulation is not a mere transitory one, which may pass away, for example, within half an hour or so after a meal; it is a much more prolonged physiological disturbance which can be traced for fully three or four hours.

I will first describe the effect of digestion on the arterial pressure, then on the capillary and venous pressures.

In Fig. 1 are recorded hourly observations of the mean arterial pressure throughout the day from 8.30 A.M. to 10.30 P.M. in a subject leading an ordinary quiescent life with comparative rest of the muscles. You observe that the pressure follows a rhythmical course, that there is a marked *rise immediately after each meal which attains its maximum* development in an hour and then the pressure slowly subsides. This wavelike rise and fall of the arterial pressure produced by each meal last from two and a half to four hours. I have observed that the amplitude and length of the curve are, as a rule, proportionate to the size of the meal. The observations show that the average maximum rise of the mean arterial pressure attained in an hour after a meal amounts to 15 cubic millimetres of mercury, though it may reach 20 cubic millimetres; for example, a typically normal wave should rise from 100 to 115 cubic millimetres and then gradually return to 100 cubic millimetres.

FIG. 1.

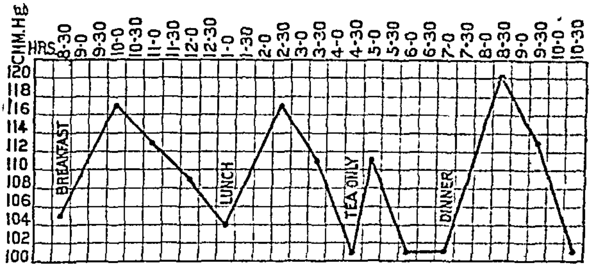

Chart showing the hourly observations of the mean arterial pressure.

Now you will naturally ask: Why should we have a rise in the arterial pressure *after meals, when dilatation* [illegible] make for a lowering of [illegible] teriometer shows that [illegible] when the splanchnic [illegible] erefore apparently a compensatory reduction of the systemic area of the circulation and the increased tonus of the arteries is one *factor* in raising the arterial blood pressure, the other being cardiac—an increase in the output of the ventricle and stimulation of ventricular contraction. These digestive waves are also present when the arterial pressure is above the normal range.

In determining the arterial pressure in clinical work a correction for the influence of digestion on the mean arterial pressure may be usefully made by applying the following rule: to deduct 10 cubic millimetres of mercury from a pressure observed within two hours after a meal and five cubic millimetres *of mercury during* the third hour. The best time to make a reliable observation of the mean arterial pressure is within an hour before a meal.

The study of the capillary and venous blood pressures during the digestive circulatory wave has likewise afforded some interesting results. The venous blood pressure is easily determined by a method of using the hæmodynamometer elsewhere described,[3] but so far no reliable method of gauging the capillary blood pressure has been suggested. I have, however, employed a method which is simple and practical, but as I hope to improve it I will not now describe it. This method has, so far, shown that the capillary blood pressure is considerably raised at the acme of the digestive circulatory wave and that it *then gradually falls during the* decline of the disturbance. The rise and fall of the capillary blood pressure therefore coincide with those of the arterial blood pressure. The venous blood pressure, on the other hand, generally falls during the full development of the digestive circulatory wave; and when it does not fall it fails to rise with the capillary and arterial pressures. These facts suggest that the venules—endowed, as you know, with muscular tissue which surely serves some purpose in the economy of the circulation—play an important part in regulating the capillary blood pressure; at one time, as at the acme of the digestive wave, contracting and so increasing that pressure and then relaxing and letting it down again. This regulating influence of the venules, however, only comes into play when the body is at rest, for it is overcome during exercise which raises both the venous and the capillary pressures together. I have just lately discovered that my friend, Sir Lauder Brunton, so long ago as in 1879 when writing on the contractility of the veins anticipated this function of the venules. "It is obvious that if venous radicles contract they may oppose a resistance to the flow of blood in the capillaries and by thus increasing the pressure within them may cause more fluid to exude from them into the tissues."[4]

---

[1] See Blood and Blood Pressure, 1901.

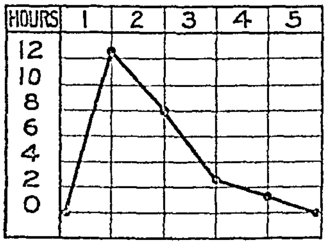
[2] Made by Mr. Hawksley, 357, Oxford-street, London, W.

[3] See the Journal of Physiology, Cambridge and London, 1902, and Blood and Blood Pressure, 1901.

Why should the capillary pressure be raised during the digestive disturbance of the circulation? As suggested by Sir Lauder Brunton a rise in capillary blood pressure may cause an increased exudation of tissue fluid. The experimental work of Ludwig and Noll;[5] of Starling,[6] of Lazarus-Barlow,[7] and of others undoubtedly supports this view and, following a new method of observation by which the tissue lymph may be measured, I have been fortunate enough to obtain confirmatory evidence of it in man. May not these periodically recurring variations of the capillary blood pressure which accompany the act of digestion be of supreme importance in nutrition? Moreover, do they not afford us a glimpse of a much broader fact than is signified by the mere act of digestion? For when food is taken there is, it would seem, not only the internal flow of the digestive secretions, but likewise a concurrent exudation into every tissue of nourishing fluid expressed from the blood into the interstitial spaces. Should further inquiry substantiate this view the physiological significance of the prolonged rhythmical movement in the circulation produced by the ingestion of food will be apparent.

In reading quite lately Pawlow's lectures on the work of the digestive glands I could not avoid observing the similarity of the form and duration of his curve of the secretion of gastric juice in the dog after a meal with the curves of arterial blood pressure incited by digestion in man —as if both were concurrent events which proceeded from the same physiological movement in the system. For the purpose of comparison I have reproduced one of Pawlow's gastric juice curves in Fig 2. I have observed that the beverages tea and coffee produce a similar rhythmical disturbance of the circulation to that which follows the ordinary meals; it is, however, less pronounced and shorter (see Fig. 1).

FIG. 2.

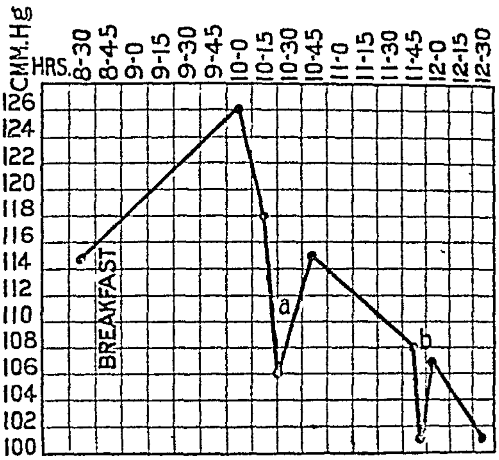


Curve showing the secretion of the gastric juice after a meal of flesh. After Pawlow.

THE INFLUENCE OF EXERCISE ON BLOOD PRESSURE.

It is now well known that the primary effect of exercise is to raise the arterial pressure, but I do not think that it is as generally recognised as it should be that this immediate rise of pressure is but temporary and is soon succeeded by a marked fall, which fall continues during the further continuance of the exercise and for some time after the cessation of it. The peripheral tubing very soon widens and the rise is thus converted into a fall. *Fig.* 3 illustrates how quickly and how effectually the mean arterial pressure may be lowered by merely throwing the muscles of the limbs and trunk into a state of contraction for short intervals. You observe two deep indentations in the curve of the digestive wave: they are the impressions made on the normal course of that curve produced by throwing the muscles into a state of sustained tension for two minutes. In spite of these interruptions the digestive wave of blood pressure continues its course, and ultimately subsides in a normal manner. The effect is therefore only temporary; but it is instructive in showing how great is the power of muscular contraction to lower the arterial blood pressure. This is the fundamental fact in resistance exercises. But this fall in the arterial pressure is but a portion of the physiological fact which we are now studying; it is simply the result of the widening of the arterioles produced by the muscular contraction—a fact which is proved by the rapid, though transitory, concurrent rise in the capillary and venous blood pressures. It therefore follows that mere static muscular contraction lets down, as it were, a large volume of arterial blood into the capillaries and in this way brings more oxygen within reach of the tissues and thus raises the metabolic processes. But it may do more than this, for by raising the capillary pressure it may greatly accelerate and increase the flow of interstitial fluid filtered from the blood into the vacuoles of the tissues and may thus flush these spaces and favour the clearing away of residue from them. From the clinical standpoint such effects as these produced by muscular action should prove useful in the treatment of diseases of the suboxidation type in which the removal of waste products is imperfect, as in chronic goutiness.

FIG. 3.



Showing the effect of two minutes' static contraction of the muscles (a and b) on the digestive curve of the mean arterial pressure.

A large group of our cases at a health resort have as a prominent feature of their circulatory disturbances a hypertonic[8] state of their arteries and arterioles and in a large majority of these cases the mean arterial pressure is considerably raised. In some such cases both the capillary and venous pressures are lowered together, showing the predominance of arteriolar contraction, while in others the capillary pressure is raised along with the arterial while the venous pressure is lessened, indicating the preponderance of venular contraction. Now, in such cases the pulse is generally felt to be small and is often reported as feeble and the hands and fingers are apt to be clammy and cold and sometimes they may even afford a cold fish-like impression to the touch, but when the capillary pressure is raised the hands are generally warm. The unguarded physician is apt to regard these signs as indicating a feeble heart and a weak circulation, and when he places his hand over the apex and finds it displaced outwardly he is confirmed in that view. In many such cases the heart muscle remains unaffected but in nearly all the second aortic sound is markedly accentuated. In nine out of ten such cases the trouble originates in the periphery of the circulation. The physiological tonus of the arteries, arterioles, and venules has passed the normal bounds and become pathological. There is, in fact, a persistent hypertonic condition which often threatens to overmaster the ventricle. The embarrassment is peripheral, and the bravely acting heart muscle is apt in time to yield, and, indeed, does very frequently yield, and then there is established a new centre from which a fresh series of [illegible] ...e majority of [illegible] at a well-eq[illegible] disordered peripheral mechanism; and then the blood-pressures (arterial, capillary, and venous) either approximate to their normal relationship to one another or they become normal. Then it becomes after the course of treatment a matter of some importance to suggest such simple methods of preventive management as may be easily followed up at home so that the benefit acquired from the visit may be maintained. Among other measures designed to this end I have found static or tension exercises of considerable value. At first the duration of the sustained tension of the muscles should be brief—so as not to be irksome—and as time goes on it should be lengthened. The exercises should be practised perseveringly at all odd times and seasons, but especially during the hour before every meal—this being the time when nature herself produces a normal fall in the arterial blood pressure. It is interesting to find how such exercises will frequently warm the extremities. One patient (a medical man) volunteered the remark that in his case the effect resembled that of a dose of nitro-glycerine; and that reminds me that Brunton and Tunnicliffe suggested in a recent article that muscular contraction may produce some product which possesses the property of dilating blood-vessels.

---

[5] Zeitschrift fur Rationelle Medicin, 1850, Band ix., S. 52.

[6] Journal of Physiology, Cambridge and London, vol. xvii.

[7] Ibid., vol. xvi.

[8] The convenient term "arterial hypertonus" was first employed by Dr. W. Russell (THE LANCET, June 1st, 1901, p. 1519).

It is apparent that the ultimate physiological effect of muscular contraction on the circulation is much the same as that induced by warmth—namely, a widening of the peripheral channels and a consequent easing of the work of the heart and a proportionate lowering of the arterial pressure. But beyond this result common to both there is a difference between the therapeutic effect of warmth and that of exercise, for heat merely relaxes muscular fibre, while exercise—even though tiring at the time—is followed by improved tone and vigour. It seems to me that physiology has a promising suggestion to offer to account for this difference; for Ranke showed that whenever muscles contract they absorb water from the blood. Now that water is proteid-containing water, which, after serving the immediate needs demanded by the contraction, may provide for repair and construction. So that we may say that exercise, like heat, expands the contracted peripheral mechanism and thus reduces the consequent increased arterial blood pressure, but does more than heat in providing for repair.

It is an easy matter to test this lowering effect of muscular tension on the blood pressure during the course of your examination of a case. I have frequently done so. Of course, you must see that the patient breathes quietly and regularly when he throws the muscles into static contraction. You will not uncommonly find, when the arterial pressure is raised while the venous is lowered, that after a minute's muscular tension the former will fall 20, or even 30, cubic millimetres of mercury and the latter will be doubled.

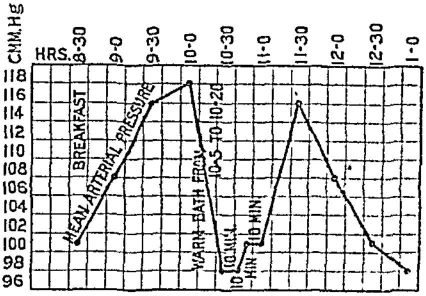
THE INFLUENCE OF TEMPERATURE ON BLOOD PRESSURE.

We now come to the third leading cause of variation in the blood pressure—namely, temperature. We are all familiar with the contracting influence of a fall of temperature on the arterial wall with rise in blood pressure and the relaxing effect of warmth with lowering of that pressure; but few of us, I think, quite realise how powerful is the influence of changing temperature, not only on the systemic blood pressure, but on all the physiological processes governed by that pressure. With a view of obtaining some evidence bearing on this point I registered daily at 8.30 every morning for over three months during last winter the mean arterial pressure and some other physiological data, as well as the temperature, as recorded in Stevenson's screen and in the room. Though these observations on the circulation were made in the house and before experiencing the influence of the outside air the record obtained was certainly instructive, for it showed that the circulatory mechanism is very sensitive to thermic variations in the weather. The record is, of course, too long to quote in detail. Suffice it to say that the average reading of the mean arterial pressure was 120 cubic millimetres of mercury for all the screen temperatures below 36° F. and 107 cubic millimetres of mercury for all those above that temperature.

Such striking effects being traceable in a normal subject we gain some notion of the disturbing influence of thermic changes of the weather on many of our sensitive patients. Thus it may be that "cold snaps" (as they are popularly called) may throw as much additional strain on a yielding ventricle as may result from an uphill walk, even though the patient be quiescent. Surely our patients suffering from arterial hypertonus need quite as much the protecting influence of an equable winter and spring as do our bronchitic invalids.

Fig. 4 shows the effect of a warm bath (temperature 100°) on the mean arterial pressure taken a little over an hour after a meal. You observe how deeply it indents the normal course of the digestive wave of blood pressure. The influence of warmth quickly passes off, as in this example. It is nevertheless a great power when judiciously directed in balneological practice. It acquires its force as a curative agent by repetition, as in a course of baths. My physiological observations have suggested that in certain cases the beneficial influence of warm immersion bathing may be enhanced by directing the patient to throw the muscles into a state of tension for short intervals during the immersion. In this way the dilating effect on the periphery of the circulation is increased and the warm bathing becomes less relaxing. I have also found it useful to direct those patients who suffer unduly from the exhausting effects of warm-immersion baths to contract the abdominal muscles frequently, so as to reduce the abdominal stasis which warmth encourages. Massage, and especially abdominal massage, is also a valuable addition to the warm-immersion bath.

FIG. 4.



Showing the effect of a warm bath on the digestive curve of the mean arterial pressure.

To return from this slight digression. Cold may raise the line of the digestive curve on the blood pressure scale, so that the commencement and the finish may read from five to 10 cubic millimetres higher than the strict normal (100) and warmth may lower these points two or three cubic millimetres. These figures furnish somewhat of a guide to the clinical correction for the effects of temperature on the arterial pressure.

It will be recognised from this sketch of the respective parts taken by these three leading causes of variation in the arterial pressure—digestion, exercise, and temperature—that the influence of digestion is paramount and constant, for the long curves of rise and fall produced by the meals recur with perfect regularity and persist beyond the temporary variations of the blood pressure produced by muscular action and by temperature, which therefore modify the line of these curves in a mere transitory way.

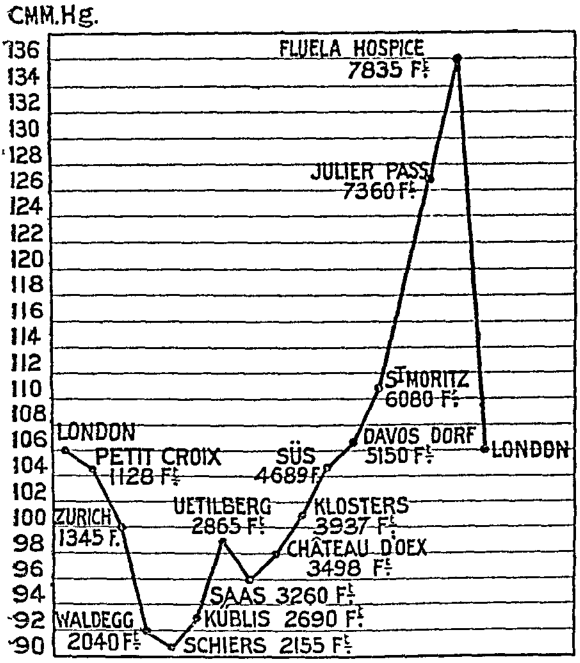
THE INFLUENCE OF ALTITUDE ON THE BLOOD PRESSURE.

In the winter of 1899-1900 I made some observations at Arosa (5800 feet) in Switzerland on the mean arterial pressure with the view of ascertaining the effect of altitude upon it. These observations led me to conclude that in the winter months the blood pressure is raised in high altitudes. Inasmuch as intensely cold weather prevailed during the visit I could not on that account regard my observations as altogether conclusive, especially, too, as other observers were led to believe that altitude lowered the blood pressure. Summer is undoubtedly a more suitable period of the year for observations of this kind than winter, for then there is less liability to encounter the disturbing influence of a low temperature. Unfortunately for myself, I can only make any such observations in the winter; still, even then they may prove instructive—for if it be a fact that altitude does lower the blood pressure and if that lowering influence is apparent in the cold months it should on this account be all the more readily accepted.

Having last January and February five or six weeks at my disposal I spent them in Switzerland, where I made a large number of observations at different altitudes, and at some (Château d'Oex, St. Moritz, Zürich, Klosters, and Süs) the blood pressure was taken at different times. At Château d'Oex (3498 feet) and at St. Moritz (6080 feet) serial observations were made at 8.30 every morning in a warm room and a number of digestive waves were recorded, and the effects of exercise on the blood pressure at these altitudes were also determined. Having previously to the visit made a large number of observations of the blood pressure under the same conditions at home I had the advantage of having a well-worked-out standard for comparison. Besides these observations on myself I made others on another subject, on many visitors, and on some residents.

Now what is the teaching afforded by the three groups of the observations—namely: (1) those made apart from the influence of digestion and exercise; (2) those afforded by the digestive waves; and (3) those furnished by exercise? In Fig. 5 are plotted out the mean arterial pressure determined at 8.30 A.M., or an hour before a meal, in a state of rest in London and at 14 different altitudes, advancing progressively from 1128 to 7835 feet. You will observe that at about 1000 feet there is no appreciable change; that a marked fall is apparent when a little over 2000 feet is reached; that at 3500 feet (Château d'Oex) the blood pressure, though somewhat higher than at the lowest point reached, is much lower than at home; and that above that altitude (3500 feet) there is a rise progressive with the altitude until we reach the highest point, the Fluela Pass (7835 feet). The digestive waves of blood pressure at Château d'Oex began at, and fell to, a much lower point on the blood pressure scale (97 cubic millimetres) than at St. Moritz (110 cubic millimetres). The effects of exercise on the arterial pressure also show that the pressure is lower at Château d'Oex than at home or at St. Moritz and that it is higher at St. Moritz than at home. At home the usual effect of active exercise is to cause a fall of my arterial pressure to 97 cubic millimetres (observed just after the exercise is over). At Château d'Oex a similar amount of exercise reduced the pressure to 92 cubic millimetres, but at St. Moritz I could not diminish it below 105 cubic millimetres.

Fig. 5.



Showing the mean arterial pressure taken at 8.30 A.M., or an hour before a meal, at various altitudes in Switzerland in January and February, 1903.

After completing the foregoing observations I made some interesting readings of the arterial pressure at Zürich where there is a railway which ascends in half an hour from 1345 feet (Zürich) to 2865 feet (Uetliberg) with a midway halt, 2040 feet (Waldegg). The uniform temperature and rest of the railway carriage afforded the most favourable conditions for comparable observations of the blood pressure. The results furnished by the up and down journeys, which corroborate each other, appear in Fig. 5 and confirm in a general way the previous observations made at similar altitudes. The concurrent testimony of all these observations made in winter points, I think, to the conclusion that altitude does lower the blood pressure within certain limits—and especially so between 2000 and 3500 feet—above which the pressure rises.

When one thinks of it, it is surely improbable that altitude should either lower or raise the blood pressure progressively throughout all gradations, for in either case life would soon be threatened or would cease. We know that nature when dealing with organic life does not, as a rule, work in straight lines; it is but the limitations of our view that give us that impression. She is ever deviating by her corrections to her beneficent ends. We should not, therefore, be surprised by this contrary effect of altitude on the blood pressure, as it is apparently but an example of this universal law, for the observations suggest that at a certain point the lowering influence of the reduced atmospheric pressure is met by an adjustment on the part of the organism. How is this adjustment brought about? The observations show that in the higher altitudes (6000 feet, as at St. Moritz) the heart's action is more frequent and the calibre of the arteries is somewhat smaller than in the lower elevations (3000 feet or so, as at Château d'Oex). The morning observations give an average pulse-rate of 76 at St. Moritz and of 71 at Château d'Oex and an average radial calibre 0·4 millimetre less at the former than at the latter place. I think we may therefore conclude that the progressive rise in the mean arterial pressure observed in the higher elevations is the result of an increase of the output of the heart and of the normal tonus of the arteries. Observations at St. Moritz on several visitors—even on those who had been sojourning there for two and three months—and on one whom I had observed at Château d'Oex were exactly similar to those on myself; but those made on a few natives showed that the mean arterial pressure in them was lower—in fact, it was much the same as in England. From this it may be inferred that acclimatisation in a high altitude is not a question of a few months only.

I am sorry that I could not prolong my visit so as to extend these observations to other altitudes and to verify or to correct those already made by repetition, and I regret this the more because at the highest point reached—namely, on the Fluela Pass (7835 feet)—it seemed to me as if a second compensation, having for its object a reduction of the blood pressure, were coming into play—namely, a vagus effect. I hesitate to mention this single observation as there may be nothing in it. I was, however, struck with the fall of 10 beats per minute below the average pulse-rate which I had observed at St. Moritz, as a slow pulse at the highest altitude reached seemed to be somewhat noteworthy. Should a vagus effect develop in still higher elevations it would, of course, counteract the rise of blood pressure maintained by a further increase of the arterial tonus and might afford a suggestion as to the cause of that mysterious ailment "mountain sickness."

I merely give you my limited observations, which without further extension you should regard as but tentative, though they were made with care so as to exclude fallacies as much as possible. I trust that other observers may be induced to take up this work and to report their results. Climatology is sorely in need of exact physiological data and we cannot have too many good observers. I think it is highly probable that in the warm months the lowering influence of altitude on the blood pressure may extend to a much higher limit than my observations made in winter indicate, for warmth reduces the arterial tonus. But so far as these observations go I am inclined to think that they have a suggestive bearing on practical climatology. I am not aware of a climatic condition that will lower the mean arterial pressure to the same extent as the medium altitudes. Why should we not think of this when deciding where to sent some of our patients with *plus* arterial pressure in the winter months? Then, again, our colleagues at Aix-les-Bains and other bathing resorts abroad for the gouty wisely advise their patients after the course to resort to a moderate altitude for their "after cure"; now according to these observations this advice may mean that the effect of the baths in lowering the arterial pressure will be maintained until the patient has recovered from the strain of the treatment. Then there is a thought that will occur to you in connexion with the higher blood pressure maintained in the winter by the higher altitudes. These should be well adapted to the climatic treatment of cases which require construction and repair, such, for example, as the phthisical, and should be contra-indicated in cases in which the removal of waste products should be the keynote of treatment, such as in gout and chronic Bright's disease, and should be further contra-indicated when we cannot be sure that the heart muscle will safely bear the additional strain of a high altitude.

[The address concluded with some remarks on the clinical value of determining blood pressure and on the importance of adopting such methods of observation as exclude the personal equation as much as possible and render clinical data equally appreciable to all.]

PARASYPHILIS.[1]

Delivered before the Fourteenth International Congress of Medicine held at Madrid in April,

BY GEORGE OGILVIE, B.SC., M.B. EDIN., M.R.C.P. LOND.,

PHYSICIAN TO THE FRENCH HOSPITAL AND SENIOR PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE, LONDON.

WITH an Apollonian "Inventum medicina meum est," Fournier proclaims himself the "inventor" of parasyphilis. Indeed, the numerous contributions to the subject which have followed the publication of his work in 1894 seem to me more or less μιᾶς φωνῆς πολλαὶ ἀντανακλάσεις—the re-echoings of his powerful and far-reaching voice. Thus to discuss the principles of the doctrine and its bearing on retrospective diagnosis and treatment means nothing else than to discuss the principles laid down and the conclusions drawn in Fournier's writings. I am therefore justified in closely following and limiting myself to his line of argument. Dr. Edmund Fournier's book on the same subject I shall treat as one of his father's, as he himself declares, "que so[illegible]" [illegible] philitic in ori[illegible] eatures are th[illegible] e met with independently of syphilis; they may be due to other causes as well, they are *banal*,[2] while syphilitic lesions, properly so-called, such as mucous patches and the gumma, are never produced outside the domain of syphilis. 2. The so-called specific drugs—i e., mercury and iodide of potassium—have a totally different influence upon parasyphilitic affections from that which they are known to exercise upon true syphilitic lesions. "There is really an abyss between the one and the other." These drugs are said to have either no effect at all upon parasyphilis or the effect is slow and incomplete, while in the case of syphilis proper it is "rapid and efficient." "These two principal features," according to Fournier, "seem to establish a well-marked line of demarcation between syphilitic affections proper and the so-called parasyphilitic ones."

If from a clinical point of view the specificity of the mucous patch[3] and the gumma has to be granted there still remain among true syphilitic lesions a great many which, to use Fournier's own words, are "banal and borrowed from ordinary pathology." As such he himself mentions the disturbances of the general health, *fever, anæmia, asthenia, wasting, cachexia, &c.*, as well as aches and pains, neuralgias and neuroses, which have nothing specific besides their origin. He also mentions rashes of the skin, so similar to, and so much resembling, common rashes that t[illegible] to differentiate betwe[illegible] yet truly syphilitic le[illegible] Hutchinson has made the remarkable statement that all the various phenomena of disease due to syphilis are imitations of other non-specific type forms. "We have," he says, "absolutely no malady which is peculiar to syphilis." Without going so far it will have to be granted that, apart from those mentioned by Fournier himself, numberless affections, such as iritis, choroiditis, hemiplegia, paralysis of single nerves, transverse lesions of the spinal cord, &c., present nothing specific apart from their origin. Nobody would think of excluding all these manifestations of true syphilis from the domain of syphilis proper under some other name for the sole reason that they are "banal." Moreover, there is among those who grant the specificity of certain syphilitic affections a great diversity of opinion [illegible] n—viz., [illegible] e, inter- [illegible] e state- [illegible] to base the diagnosis of inherited syphilis on this symptom alone. It is the same with the notched teeth which go by his name. And with regard to either symptom he has many convinced followers. According to Fournier, and perhaps the majority of syphilographers and ophthalmic surgeons of our time, both symptoms are to be met with in other diseases besides syphilis, they are "banal." Interstitial keratitis is to some nothing but an expression of impaired nutrition, to others as frequently of tuberculous as of syphilitic origin. Leucoderma is given by Fournier as the classical prototype, the type *par excellence*, of a parasyphilitic lesion. On the other hand, I. Neumann of Vienna says that there exists at present only one opinion—viz., that leucoderma is *absolutely* characteristic of syphilis. Very few, I believe, will not subscribe to this statement. Opinions are likewise divided with regard to ophthalmoplegia externa, to the skin infiltration of the newly born, to certain forms of choroiditis, to spastic spinal paralysis, &c. On the other hand, it seems that at least one [illegible]

reference to gumma of the palate 44 per cent. were [illegible] esses that this pro- [illegible] *taking into account* [illegible] alls "*la chance des* [illegible] or identity of a number of consecutive cases—he proposes to reduce it and even to diminish [illegible] ordinary scale [illegible] sequence. Tha[illegible] syphilitic his[illegible] Fournier, is [illegible] are less than [illegible] one takes into consideration the mental state of some of the patients on whom we have to rely for their previous history—"without mentioning all the cases of syphilis abnegated or wilfully concealed, of syphilis overlooked or unnoticed, also the cases of conceptional hereditary syphilis"—one would scarcely be surprised to find the final figures on the *other* side of a hundred, in the same way as the addition of certain mortality statistics leads to figures in excess of the birth-rate. I may be allowed to remark that from my own experience, which extends over more than 140 hospital and no small number of private cases, I am personally convinced of the important part which syphilis plays in the production of tabes without, however, going to extremes or even believing that the question has been finally settled. Different observers from different parts of the world have pointed to the non existence or infinite rarity of tabes in districts where syphilis rages endemically. At the first glance this seems to be a very strong argument against the specific origin of tabes. Yet it has to be borne in mind that exactly the same has been reported with regard to other affections, which in our climes at least are undoubtedly a frequent consequence of syphilitic infection, such as diseases of the eye. How far functional use or "irritation" influences the localisation of the noxious effects of the syphilitic poison we do not know. With the present state of our knowledge we must confess that certain facts in the pathology of tabes are only with great difficulty, if at all, reconcileable to the doctrine of its syphilitic origin. Anyhow, it seems strange to call an affection "specific" which in its antecedents lacks evidence of syphilis in from 22 to 44 per cent., while another should be "banal" with less than 10 per cent. I am not aware that this strange contradiction has been pointed out before, much less that it has been satisfactorily explained. In his recent careful and interesting statistics of tertiary syphilis Neisser gives the percentage of those who present tertiary symptoms without a history or evidence of previous infection at about 50. How can it, then, be explained that an affection likes tabes, which after all belongs to the late sequelæ of the disease, should in its previous history afford evidence of syphilis with such astounding frequency? The only explanation which presents itself to my understanding is that some seekers after syphilis will seek and find even an "absent argument." For general paralysis the percentage is by several authors given as high as for tabes. The obvious consequence would be that the disease cannot be called "banal." Banality, one of the "characteristics" of parasyphilitic affections, is, as we have seen, not an attribute of all of them, while it is an attribute of numberless syphilitic affections. Which particular affections are to be considered specific, which "banal," is, after all, to a large extent a matter of personal opinion. Anyhow, the most banal of lesions may be and frequently is syphilitic.

---

[2] It is strange to find Fournier constantly using a term against which he has so long and so vehemently waged war.

With regard to the second "characteristic"—the influence of specific drugs—it must be admitted that this seems only a question of degree. Of course, in many syphilitic affections the effect of mercury and iodide is "at once intense and rapid." But I am not going to enumerate all those in which it is slow, little, or none. Quite apart from cases of idiosyncrasy to the drugs, or cases of malignant syphilis, one has only to think of the many disappointing results in cases of hemiplegia, choroiditis, ophthalmoplegia, spastic spinal paralysis, &c., to realise the incongruity of making the effect of the drug a criterion of the nature of the disease. On the other hand, it is not generally admitted that specific drugs are powerless in leucoderma, tabes, and general paralysis. Good results have been reported in general paralysis and in tabes which unfortunately I have never been able to obtain. Fournier himself has had most satisfactory results, amounting to *complete cures*, in cases of parasyphilis, where one would expect them least—viz., in certain heredo-syphilitic dystrophies—and he advocates mercurial treatment in most cases in which parasyphilitic affections are met with in children only suspected of heredo-syphilis. "Those who think that the result of treatment by specifics may be relied upon as establishing the diagnosis may easily make great mistakes. Syphilitic affections often resist treatment for a long time (I may add, even altogether) and, on the other hand, mercury and iodides often effect the greatest possible good in cases which are not syphilitic" (Hutchinson). How, then, could a "characteristic" of this kind be of use in drawing a line of demarcation between two classes of affections supposed to differ in nature? Later on I shall have to say a word on the "nature" of parasyphilitic affections in general. Of the arbitrariness which must of necessity reign in allotting a certain disease to one of the two classes of affections I want to give at least one instance. Interstitial keratitis, according to Fournier, is not necessarily syphilitic, an opinion in which I concur. All will agree that if at all it is neither rapidly nor intensely influenced by drugs. Its course may be shortened and attenuated, but on the whole it is an affair of many months, whether treated by specifics or not, it is never cut short by them, and with the most energetic treatment is often extremely tedious. Yet this affection, bearing both the characteristics of parasyphilis, is not classed under the latter. This example conclusively demonstrates that either of the two criterions taken singly, or together, is utterly unfit to decide anything respecting the nature of the disease. Take, for instance, a case of spastic spinal paralysis, or of choroiditis (both "banal" affections) of undoubted syphilitic origin, as proved by the co-existence of such specific lesions as a gumma, which latter disappears under specific treatment, while the paralysis or the choroiditis remains little or not at all influenced. Such cases abound. Was the "banal" affection syphilitic or parasyphilitic? It was, of course, syphilitic, although it bore both the characteristics of parasyphilis—viz., banality and refractoriness to specific treatment. The classical type of parasyphilis will, after all, be a scar left by some ulcerative syphilitic process—for instance, an ulcerative gumma. Here we have a lesion of undoubtedly syphilitic origin and possessing the qualities of banality and refractoriness to treatment. If one were to object that a scar cannot properly be called an "affection," it has to be remembered that the terms "affection," "stigma," and "lesion" are all through used promiscuously by Fournier. A scar certainly is a stigma, and intra-uterine amputation stumps or dental erosions are no more "affections" than scars are. But there seems no need for inventing an extra name for a scar left by a pathological process, nor can anything be gained by huddling together distinct pathological processes—as, for instance, pneumonia, corneal ulcer, &c., when due to the same cause, e.g., measles—under the denomination of parameasles.

With regard to the parasyphilitic affections following acquired syphilis I shall have to say only a few words. The connexion of tabes and general paralysis with syphilis seems to me established by carefully and critically sifted clinical evidence. Nothing of the kind can be said of any other parasyphilitic lesion attributed to the acquired disease, such as neurasthenia, hystero-neurasthenia, hysteria, epilepsy, &c. Of course, in a neurotic person syphilis may, and will, like any other disease, play the part of *agent provocateur*. In this way syphilis will be responsible for many manifestations of the variegated disease called neurasthenia. But so will gonorrhœa, or a cold, or any other complaint befalling a neurotic person. To give an idea of the degree to which syphilis may react on the mind and consequently on the nervous system Fournier cites the case of a young man who on being told that he had an indurated chancre immediately went home and hanged himself. Of course, suicide here seems parasyphilitic *par excellence*, although parasyphilis at a remarkably early stage. Its syphilitic origin is beyond doubt, it is eminently "banal" and past cure. A similar event has quite recently been reported by another eminent syphilographer in a case of gonorrhœa. It would seem odd to describe it as paragonorrhœal, yet there is apparently no reason why the frequent and profound disturbances of psychical functions following this disease, particularly in its chronic stage, should be treated differently from those caused by syphilis. In the new "Traité de Syphilis" by Fournier the functional disorders of the nervous system during the secondary stage are treated at considerable length. Here they are described as syphilitic and specific treatment is urgently recommended as the only and certain remedy. In his book on parasyphilis the identical nervous disorders are treated at the same length and the complete inefficacy of specific treatment is given as proof of their parasyphilitic nature. It seems that exactly the same nervous complaint during the same stage may, in his opinion, be either syphilitic or parasyphilitic, either only curable by specifics or not at all. That strange symptom boulimia, as a manifestation of syphilis, although by no means unknown in the country of beef-eaters, appears in the "Traité" as a syphilitic disease, the symptom of a "diathesis, which requires the treatment necessary for that diathesis and nothing more." In the work on "Parasyphilis" this very same boulimia appears (in a footnote) as a parasyphilitic affection the characteristic of which is not to yield to specific treatment. Evidently we are to understand that during the secondary stage of syphilis there is a boulimia syphilitic, and apart from it a boulimia parasyphilitic, both affections "banal," the one curable and curable by mercury alone, the other not amenable to mercurial treatment. Such incongruities are the natural outcome of the capricious principle underlying the whole division between syphilitic and parasyphilitic lesions.

The seed of parasyphilis has yielded a much richer harvest in hereditary than in acquired syphilis. If one looks at the list of parasyphilitic affections attributed to the influence of syphilis on the offspring one is at once struck by the variety of the pathological conditions which meet the eye. There are inflammatory processes, progressive degenerations, dystrophic conditions, dyscrasias, scars, tumours, predispositions, anything from a slight anomaly to monstrosity, from intellectual weakness to complete absence of the brain, from simple uncomplicated debility to "*la morte banale*," moreover moral defects, functional disorders, diatheses, &c. The method by which this ubiquity of syphilis is established is very simple. Every pathological condition which is "banal" and not rapidly and intensely benefited by mercury found in a heredo syphilitic subject (or one suspected of heredo syphilis for the reason that one of the parents or grand parents has at one time suffered from syphilis) is registered as parasyphilitic, and subsequently the cases are arranged under different pathological headings Of course in this manner a fairly large number of cases have been collected in which congenital syphilis or a history of acquired syphilis in parents or grandparents has been co existing with nearly every imaginable pathological condition But co existence is *not causal connexion, and the question of origin, to be* satisfactorily answered, requires much more subtle methods than compilation, enumeration, and registration

Here I wish to take up the thread where it was dropped at the last International Congress in Paris One of the subjects for general discussion there was the state of health of the descendants of parents who had themselves suffered from congenital syphilis Some time before the discussion took place Professor Jullien of Paris had addressed an appeal to all specialists, French and foreign asking for their personal *experience on the subject The result of this collective* investigation, although instigated by a member of the profession so widely known and so highly esteemed and on such an important occasion, has been a complete failure In the list of those who answered the appeal nearly all the foremost names of Europe and America were missing This fact alone is, I think, a certain indication that to the majority of our most experienced specialists the deleterious influence of syphilis on the third generation was an unknown quantity Of the 45 observations *sent in to Professor Jullien* 12 are *negative the* remaining 33 being mostly of such a shadowy nature that exposed to the searchlight of sound criticism they have to vanish into nothingness, the remaining few are open to more than one interpretation and—of course a most important point—are too small in number to prove any thing at all If syphilis had an appreciable effect on the third generation this would show itself in more than a handful of cases Some years ago I pointed out in a paper on the transmission of syphilis to the third generation the *extraordinary difficulties which lie in the way of proving* such transmission even if one limits oneself to syphilis proper Obviously the difficulties are increased a hundredfold

yphilitic" affections a
n the production of
be operative not even
to be guessed at in the present state of our knowledge The question put by the last International Congress has remained unanswered At present the value of parasyphilis as a means of retrospective diagnosis respecting the third generation is *nil*

Of course, there is more chance of attaining tangible results by setting the mark somewhat nearer and limiting oneself to the next generation I do not deny nor do I doubt, that several of the affections classed by Fournier as parasyphilitic are really of syphilitic origin For instance, there is scarcely any doubt o
being in no small number of
But why call them "parasyp
lish a distinction between
meningitis the one syphilitic, the other parasyphilitic as Fournier does? There is no need for any such division, either from a clinical or an anatomical point of view The more or less marked effect of mercury, the more or less "specific

domain of syphilis but I have met them in a case of undoubted congenital syphilis, in a set of teeth otherwise perfectly shaped and also in another equally certain case in which several subsequent children were affected in exactly the same manner I should be loth to call a stigma of such value and precision parasyphilitic and to class it with a pile of insignificant dental malformations to be met with every day and in every state of health Of course it is not amenable to specific treatment any more than the remains of any pathological process which has come to an end—as for instance, a scar Tabes and general paralysis also are as I said before in all probability closely related to syphilis and when met in children (a rare occurrence) strongly suggestive of hereditary taint Whether in the end they will turn out to be one and the same process only differing in localisation as many believe or whether they will have to remain two distinct maladies is still a matter of doubt I do

n
h
t
T
call "heredo syphilitic,' whatever their "nature" may be, will undoubtedly allow a retrospective diagnosis, if not with absolute certainty, yet with more or less probability, according to the accompanying circumstances But with regard to the rest of this pathological medley—such as strabismus, hysteria, toothgaps cataract, giantism moral gaps, *astigmatism, headache* and such like—*even if they were* occasionally produced by parental syphilis, are utterly worthless for retrospective diagnosis as well as for prospective treatment Parasyphilis might be called a pathological lumber room there may be a few valuable pieces in it but the greater part is worthless

On the question of malformations as caused by syphilis I want to say a final word which to a greater or less extent
hilitic' lesions To

were caused by hereditary
find them with greater fre
quency where syphilis for several generations has been raging endemically The recent investigations of During in Asia Minor have proved nothing of the kind Likewise in rural districts, where syphilis is not as frequent as in Paris, its disfiguring influence on the offspring should be less On the other hand it is emphatically stated that the same malformations in man are produced by other agents such as alcohol tuberculosis nervosity (*la famille nevropathique*) acute infectious disease &c In these circumstances in order to demonstrate the syphilitic factor in the causation of these terata it would be indispensable to collect such cases in which these other factors can be eliminated with at *least some degree of probability* Nothing of the kind is even attempted The clumsy statement of occasional coincidence is offered as proof of causal connexion. It has to be granted that such an attempt would meet with nearly insuperable difficulties due to the practical impossibility of collecting sufficiently complete and reliable family histories extending over several generations and also to the co existence of several of these factors in nearly every individual case But even if this impracticable task could be accomplished for a number of cases with regard to the *different toxic agents*—even if we could exclude these sources of error—nothing much would be gained because the manifold causes of malformations are for the most part still buried in a "profound sea" of ignorance To "exclude'

what is hidden in its "unknown fathoms" is, of course, a matter of impossibility. The little which at present we dimly discern of these "secrets of the deep" is not such as to prop up any hypothesis which attributes a considerable share to toxic influences. The "strange issues" of animal birth are not less frequent in all those species which are unexposed to syphilitic or tuberculous infection or to alcoholic intoxication. Certainly they may have toxins of their own with regard to which we are "unobnoxious to be pain'd." Moreover, the "mechanics of evolution" have brought to light many interesting experimental facts regarding the mechanical causation of deviations from the normal course. Finally, phylogenetic reminiscences in ontogenetic evolution seem the foremost factor where the abnormal can be traced back to anterior or lower types. There is, perhaps, although it may sound paradoxical, a large physiological factor in the production of malformations which are commonly considered as pathological only. Anyhow, the whole question is of such extent and depth that it has to be looked upon from an elevated biological standpoint and not through the peephole of a speciality such as syphilography. We are standing just on the threshold of teratology, and we see that the causes which are operative in diverting embryonic development from its normal course are of infinite variety and complexity, for the most part at present beyond our power of conjecture or divination. We know that toxic influence is a factor which plays a part in it, but how large this part is, and whether the syphilitic poison is one which acts in this manner by intra-uterine intoxication, we do not know.

The inconsistency of the theoretical foundation of the whole doctrine is best illustrated by the practical conclusions drawn from it. We have been told that specific remedies either have no influence at all upon parasyphilitic affections or, if they have, "they act very slowly; in fact, their therapeutic action is *always incomplete and insufficient*." This was, in fact, one of the characteristics upon which the whole distinction was founded. Yet we are told in the end that experience is above theory and that it teaches us that specific treatment has *very often* cut short, palliated, and corrected, and even absolutely cured, certain syphilitic dystrophies, and in corroboration of this statement several cases are given in which the effect of specific treatment was not only *sufficient* but *complete*. I may be allowed to say that in this case it seems not to be the superiority of experience in general over theory in general, but the inferiority of this particular theory of parasyphilis which has to be held responsible for the contradictions to which it leads. If a theory is found to be diametrically opposed to practice the blame cannot be thrown on theory as an abstract while the theorist makes his escape. The theory of parasyphilis is bound to lead to direct opposition with facts, because the premisses upon which it is reared are fallacious and because it is based on a wrong notion of specificity.

Of course, it is out of the question to give general rules for the line of conduct to be followed with regard to treatment. A dental erosion, rickets, nævus, hydrocephalus, strabismus, tabes, hæmophilia, a predisposition to tuberculosis, &c.—all declared to be parasyphilitic conditions—will give different therapeutic indications. It therefore seems to me the crown-stone to the whole edifice of parasyphilis when Dr. E. Fournier gives general therapeutic rules—supposed to be binding, no matter what particular affection may be present in any individual case. As an example I give here the third of these therapeutic indications: "When a child is born where there is a previous history of syphilis in the parents, and who presents this or that stigma, the only thing to do is to place the parents under a prolonged anti-syphilitic treatment." When the parents are syphilitic mercurial treatment is certainly indicated "with the object of exercising a permanent influence on subsequent pregnancies." But it would seem exaggerated prudence to put both healthy parents on prolonged mercurial treatment merely because a child has bad teeth, or strabismus, or a nævus. On the other hand, meningitis or tabes may, perhaps, justify such a course. But in an *omnium gatherum* like parasyphilis it can never be a question of "this or that"—every fact has to be examined separately and to be treated according to its own merit. In like manner the question of treatment for the parasyphilitic himself will have to be answered according to the particular form of his parasyphilis. A case of parasyphilitic giantism, for instance, may without the least scruple be put on mercurial treatment with the object of reducing his size, likewise the corrective effect of the drug may be tried in cases of moral perversions of heredo-syphilitic origin, while in such parasyphilitic affections as congenital amputation, imperforate anus, double or triple tongue, &c., specific treatment will be of no avail.

The idea underlying the doctrine of parasyphilis is not new. Any specific disease may, and often does, lead to sequelæ void of all specificity in the same way as, to use Mr. Hutchinson's happy parallel, war may, and often does, lead to famine. Under different names, such as quaternary syphilis, pseudo-syphilis, post-syphilis, &c., exactly the same idea has at different times made its appearance in the history of syphilography. What is particularly new in the modern teaching of parasyphilis is, apart from the name, the enormous extension given to the deleterious and deteriorating influence of syphilis upon the race. With regard to this point I wish to give unmistakeable expression to my firm conviction that the modern doctrine of heredo-parasyphilis contains "one inch of discovery" to a "South Sea" of "invention."

A STATISTICAL INQUIRY INTO THE PROGNOSIS AND CURABILITY OF EPILEPSY; BASED UPON THE RESULTS OF TREATMENT.[1]

By WILLIAM ALDREN TURNER, M.D. EDIN., F.R.C.P. LOND.,

PHYSICIAN TO OUT-PATIENTS, THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, AND TO KING'S COLLEGE HOSPITAL.

Introduction.—Much attention has been given from classical times onwards to the prognosis of epilepsy. It would, however, serve no useful purpose to refer to the numerous authorities on this disease, or even briefly to state their conclusions. An exception ought, however, to be made in the case of Hippocrates, in whose writings will be found much that is of value even at the present time. For example, when describing the "Sacred Disease" he wrote:[2] "If it attacks little children the greater number die. ..... If youths and young adults, recovery may take place, but there is danger of its becoming habitual, and even increasing if not treated by suitable remedies. Such also is the case when it attacks children. ...... When it attacks people of advanced years it often proves fatal. ...... When a person has passed the twentieth year of his life the disease is not apt to seize him, unless it has become habitual from childhood. ...... When the disease has prevailed for a length of time it is no longer curable." It would appear, however, as if the ancient Greek and Roman physicians took a more generally favourable view of the disease than has been the custom, in more recent times. The essentially gloomy view of the prognosis which has attended the study and treatment of the malady up to the present time may be largely ascribed to the writings of the French physicians in the earlier decades of the last century. Gloomy indeed is the general impression obtained *from the* writings of Maisonneuve (1803), Pinel (1818), Esquirol (1838), Valleix (1851), and others. More cheerful are the results recorded by such writers as Herpin (1852) and Trousseau (1861) in France and Russell Reynolds (1861) in this country, who corroborate the opinion expressed by one of the earliest of the French authors, Tissot (1778–80), who almost alone in the eighteenth century stated that he had cured a great number of epileptics and believed that much could be done towards the arrest of the malady.

A few statistics on the subject may be given here with a view of showing the variability existing between the results obtained by treatment at different periods. In the pre-bromide days it is interesting to recall the high percentage of so-called cures which have been recorded; thus Hufeland[3] stated that a cure was effected in 5 per cent. Russell Reynolds[4] noted that 10 per cent. of his cases.

---

[3] H[illegible] 1841.

[4] I. [illegible] 361.

of his cases were cured; Trousseau obtained 20 cures out of 150 cases, or 13 per cent.; and Herpin[5] was perhaps justified in his sanguine belief when he recorded 19 cures out of 38 cases, or 50 per cent. These are the results recorded by physicians who used remedies (such as oxide of zinc and nitrate of silver) which have *long ago* passed out of present-day practice. The almost universal administration of bromides, since their introduction in 1857 in the treatment of this disease, has in no way affected the variability in the results obtained. To mention a few instances: Nothnagel gives from 4 to 5 per cent. of cures, Laehr gives 6 per cent., Ackermann gives 7·6 per cent., Dana[6] gives from 5 to 10 per cent., Wildermuth gives 8·5 per cent., Habermaas[7] gives 10·3 per cent., and Alt gives 12·5 per cent. It must be evident that some explanation ought to be forthcoming as to the difference existing between the statistics of recent authors upon the results obtained before and since the introduction of the bromide treatment. First, some proportion of the existing difference is accounted for by the greater precision exercised in diagnosis, the later authors excluding all cases from their statistics of symptomatic epilepsy, or epilepsy arising from organic cerebral or meningeal disease, and of hystero-epilepsy. It is within the knowledge of most neurologists that the prognosis of symptomatic epilepsy is more favourable than that of true epilepsy, but an obvious proof of this fact may be found on perusal of Reynolds's[8] figures, which show 10 per cent. of cures in the idiopathic disease and 43 per cent. in that due to organic cerebral disorders. Secondly, much of the discrepancy existing in statistics depends upon the definition of a cure, the interpretation differing widely in nearly every writer's statements. Reynolds regarded only those cases as cured in which there had been perfect restoration to health during a period of at least four, or at most eight, years after cessation of the seizures; but many authors fail to state in their writings what is their definition of cure or recovery from epilepsy, and in the majority of instances so-called cures are merely long remissions occurring spontaneously or induced by suitable medicinal remedies. It would seem to be obvious from Voison's statement that Herpin's were really cases of permanent cure, for he observed many of these patients 10 years after Herpin's death and found them free from fits.[9]

The statistics.—It has been thought advisable that the *records of the out-patient department of the National Hospital* for the Paralysed and Epileptic, which contain an enormous amount of valuable information in this connexion, [illegible] with a view to collecting [illegible] any years in the treatment [illegible] of the bromides and the [illegible] I am therefore greatly indebted to my colleagues in the out-patient department of the hospital for permission to refer to their case records and to add them to those which have been under my own observation. A few cases have also been obtained from private sources. I have reserved for special consideration in a further communication the cases which have come under care and treatment at the Colony for Epileptics, Chalfont St. Peter, amounting to about 200 in number. The reason for this separation is obvious, in that those cases which eventually find their way into this and similar institutions have previously to their admission been under various forms of medicinal treatment, from which they have received no permanent benefit, and have become in the majority of instances confirmed epileptics. The hospital cases, on the other hand, are mainly early examples of the disease, with little or no mental impairment, and are perfectly capable of continuing their schooling or attending to their several occupations.

In analysing the cases certain guiding principles were laid down and the following eliminations were made: (1) all cases which had not been under constant observation and treatment for a period of at least two years; (2) all cases which showed any co-existing complication, such as hemiplegia, albuminuria, or gross cerebral lesion; and (3) all cases of pronounced idiocy or dementia. By observing these restrictions cases of so-called idiopathic epilepsy were as far as possible obtained, while any transitory amelioration resulting from medicinal or other treatment was checked by *fixing the minimum period of observation at two years.* In the study of the cases the statistical method has been adopted and the results have been recorded in percentages, the total number of cases used in the construction of each table being also given. Although many objections may be urged against such a method it has been deemed to be the best available, while the results, as will be seen later, show a surprising uniformity when considered from various points of view. The total number of cases used in the investigation is 366. Of these 355 are from the records of the out-patient department of the Hospital for the Paralysed and Epileptic, while only 11 are from private sources. By far the larger proportion are out-patient hospital cases, a fact of practical importance when we consider how large a part the ordinary conditions of life, such as diet, habits, and general environment, play in modifying a disease like epilepsy. The cases have been subdivided into three groups according as they have responded, successfully or unsuccessfully, to treatment.

TABLE I., *giving the Total Number of Cases and the General Result of Treatment.*

Cases of arrest	86	Observed over nine years ...	38
Cases showing improvement	105	„ „ ...	43
Confirmed cases	175	„ „ ...	68
Total	366	Total	147

The term *arrest* has been used at the outset advisedly in preference to *cure*, owing to the uncertainty in defining the latter term. No case has been regarded as arrested which has not been free from fits for a period of at least two years. The cases classified as *improved* are those which have responded, more or less satisfactorily, to treatment. Under this heading are also included those cases in which a remission, sometimes for a number of years, has occurred, but in which a relapse has eventually taken place. *Con-* [illegible] steady tendency, [illegible] mental deteriora- [illegible] the frequency or the severity of the seizures. In the second column of the table is given the number of cases which were observed for a period of nine years or more. The importance of this column will be seen in a subsequent part of the paper. Of the total of 366 cases no less than 86 showed an arrest of the seizures over periods varying from two and a half to 25 years. The majority of these continued the bromide treatment during the whole period of arrest, so that, with few exceptions, the amelioration cannot be described as other than arrest during the administration of the bromides. In all cases, owing to the patient passing from under observation after a number of years, no further record has been obtainable. It is, however, no uncommon thing to meet with a past history of this disease in adults and elderly people suffering from symptoms of nervous debility and neurasthenia, who give an account of having many years before been subject to attacks of an epileptic nature and of which they have been cured. Two instances of this may be given.

CASE 1.—A man, when 18 years of age, had an epileptic fit. This was followed by two more attacks during the next 18 months. He was kept upon bromide treatment for four years and as there was no recurrence of the fits the medicine was stopped. 15 years later, when aged 35 years, he came under treatment for general neurasthenic symptoms, having had no relapse of the epileptic attacks.

CASE 2.—An unmarried woman had a number of epileptic fits between the ages of 28 and 32 years. She was under treatment by bromides for one year only. 22 years later, when 54 years of age, she came under observation for headache and nervousness, having had no further attacks of epilepsy since she was 32 years of age. During this period she had no treatment of any kind.

The subjoined table (Table II.) gives the total number of cases in which arrest took place and the length of time during which no fits were noticed, the bromides being all the while administered, except where stated to the contrary.

As it is highly desirable to ascertain how far epilepsy is a disease which may be arrested, improved, or become confirmed, it is proposed to study the cases which have been collected and the influence of treatment upon them under various headings, so as to define, as far as possible, the specific factors upon which a prognosis may be based. The method adopted in this paper is one of percentages, the

total number of cases in the several tables showing slight variations, according as the information supplied by the notes threw light upon the points specially under investigation. The prognostic bearing and value of the following influences will therefore receive separate consideration.

Conditions influencing prognosis.—The prognosis of epilepsy and the conditions which influence it will be discussed in detail. It is proposed to deal with this subject under the following headings: (1) the influence of a hereditary disposition; (2) the influence of age at the onset of the disease; (3) the duration of the disease; (4) the frequency of the seizures; (5) the character and time of the seizures; (6) the influence of marriage; (7) the influence of pregnancy, parturition, and the puerperium; (8) the influence of sex; (9) the influence of the catamenia; and (10) the influence of accidental factors. After the above have received consideration on the basis of the collected cases, attention will be directed to certain types of epilepsy which have an influence on the prognosis, and also to the important subject of long remissions in epilepsy and their bearing upon the cure of the disease.

1. *The influence of a hereditary disposition.*—For the purposes of this investigation a family predisposition to epilepsy only—i.e., a similar heredity—has been noted. The influence of the neuroses, such as chorea, migraine, alcoholism, and insanity, has been for the present purpose omitted from the statistics.

TABLE III., *giving the Total Number of Cases in which this point was investigated.*

—	Arrests.	Improved.	Confirmed.	Total.
Epilepsy on mother's side	16	16	18	50
Epilepsy on father's side	12	11	14	37
No known heredity to epilepsy	42	59	24	125
No note of heredity	12	19	119	150
Total	—	—	—	362

In Table III. a total of 362 cases has been analysed; of these 150 may be eliminated, as there was no note either for or against any hereditary predisposition. Of the remainder there was a clear family history of epilepsy in 87, while the existence of this disease in the family was unknown to the patient or the relatives in 125. The malady was slightly more common upon the mother's side than upon the father's side.

TABLE IV., *giving the Percentage of Hereditary and Non-hereditary Cases.*

—	Arrests. Per cent	Improved. Per cent.	Confirmed. Per cent.	Total cases.
With hereditary history	32 0	31·0	36 0	87
Without hereditary history	33 6	47·2	19 2	125
Total	—	—	—	212

From Table IV. it is seen that there is practically the same percentage of arrests in those with as in those without a hereditary history, the latter, moreover, showing a greater percentage of improved cases and a decidedly smaller percentage of cases which eventually became confirmed.

The general prognostic conclusions which may be drawn from these cases are: (*a*) That there is as great a chance of arrest of epileptic fits in those who have as in those who have not a known family history of epilepsy. (*b*) In those who have a hereditary history the chances as to whether the fits become arrested, improved, or confirmed are in any given case about equal. (*c*) That as regards general improvement more is to be expected in those who have no hereditary disposition. (*d*) On the other hand, a considerably smaller percentage of confirmed epileptics is to be found amongst those who have no family predisposition to the disease

2. *The influence of age at the onset of the disease*.—In the subjoined table the percentages are given in the middle columns, the total numbers being stated in the last

TABLE V., *showing the Age Percentage at the Onset of the Fits.*

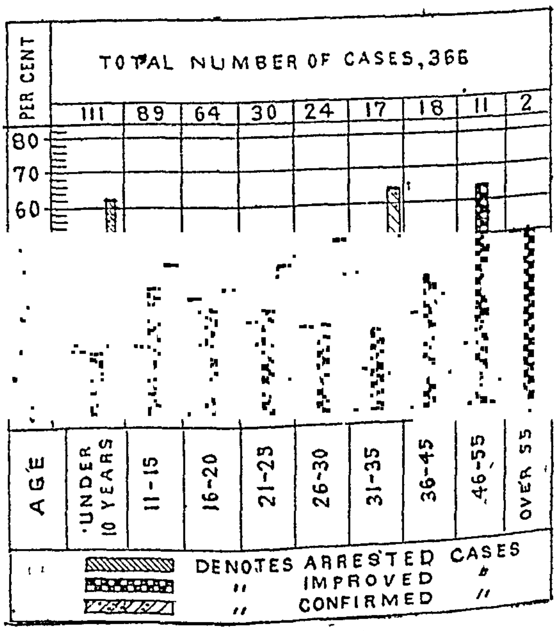
Over 55 ,, ...	50 0	50·0	—	2
Total	—	—	—	366

The accompanying chart (Chart 1) is of especial value as it shows that the age at the onset of the disease is particularly important in considering the prognosis. In order to facilitate the comprehension of the figures in Table V. the following graphic method has been adopted.

CHART 1.



Showing influence of age at onset.

The main conclusions to be derived from a perusal of the above may be stated as follows: (*a*) Epilepsy commencing under ten years of age is least favourable as regards arrest or improvement and most favourable for the production of confirmed cases. (*b*) Those cases in which the onset of the disease is between 16 and 20 years of age show the greatest percentage of arrests and the lowest percentage of confirmed cases. From this quinquennial period onwards to that of 31 to 35 there is a steady diminution in the percentage of arrests and a progressive increase in the percentage of confirmed cases. The chief point of practical importance to be deduced from these figures, if put in general terms, is that epilepsy arising during puberty is essentially a tractable disorder, while that of adolescence is resistance to treatment These facts and figures confirm in a striking manner the opinion of Hippocrates who wrote: "Epilepsy which commences about puberty is susceptible to cure, while that which comes on after 25 years of age as a rule only terminates with the patient."[10] (c) From that arising during the quinquennial period from 31 to 35 years (which provides the least tractable form of epilepsy, except perhaps that commencing under 10 years of age) there is a steady diminution in the number of cases which become confirmed, so much so that of those cases which arose during the decennial period from 46 to 55 years only 9 per cent. became confirmed epileptics. (d) Epilepsy arising over 55 years of age, to which the name of senile epilepsy has been applied by some writers, is essentially a tractable disorder.

3. *The influence of the duration of the disease.*—In the two following tables the duration of the malady is considered, the percentage frequency being given in the middle columns and the total number of cases in the last. The term "duration" signifies the course of the disease from its commencement until the patient came under regular observation and treatment at the hospital, from which time there dated either arrest of the fits, improvement, or a steady downward deterioration.

TABLE VI., *giving the Duration Percentage of the Disease up to the Commencement of Treatment and the General Result of Treatment.*

Duration.	Arrests. Per cent.	Improved. Per cent.	Confirmed Per cent.	Total cases.
10 years and under	23·5	32·3	41·1	272
11 to 20 years	25·8	19·3	54·8	62
21 ,, 30 ,, ...	12·5	20·8	66·6	24
31 ,, 40 ,, ...	20·0	—	80·0	5
Over 40 ,, ...	50·0	—	50·0	2
Total	—	—	—	365

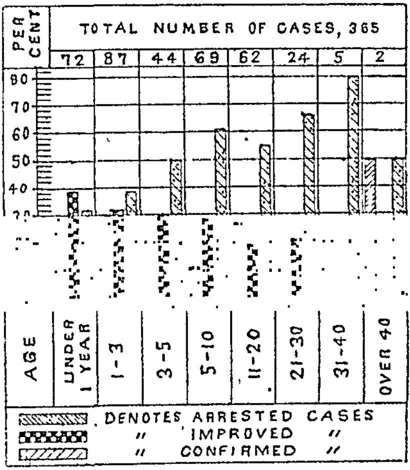
Table VI. shows, by division into decennial periods, that there is as great a percentage of arrests when the disease has lasted from 11 to 20 years as from one to 10 years, but that under 10 years the percentage of improved cases is greater and there is less tendency for the disease to become confirmed. But as 10 years is a considerably prolonged period, and as the majority of epileptics come under observation and treatment before so long a time has elapsed, it is important to ascertain the percentage frequency for periods short of 10 years, and this has been done in Table VII.:—

TABLE VII., *giving the Percentage Frequency in Four Unequal Periods under 10 Years of Age.*

Duration.	Arrests. Per cent.	Improved. Per cent.	Confirmed. Per cent.	Total cases.
Under 1 year	29·1	38·8	31·9	72
1 to 3 years	29·8	32·1	39·0	87
3 ,, 5 ,, ...	20·4	29·5	50·0	44
5 ,, 10 ,, ...	11·5	27·8	60·8	69
Total	—	—	—	272

Some general conclusions may be drawn from a perusal of the tables, as well as from a study of the subjoined chart (Chart 2), which gives in a graphic form the percentage results already detailed. (a) Speaking in general terms the earlier a case is brought under systematic treatment the more hopeful the prognosis and the greater the probability of improvement. (b) That there is a greater prospect of arrest or improvement during the first five than during the second five years of the disease. (c) Arrest of the fits, however, may take place in cases even after a duration of from 20 to 30 years. After 30 years arrest is possible, but the fewness of the cases hardly allows of any definite conclusions. (d) There is a progressive tendency for epilepsy to become confirmed the longer the disease lasts without definite treatment.

CHART 2.



Showing duration percentage.

A comparison may now usefully be made between Tables V. and VII., which show respectively the age and duration percentages, and the following table (Table VIII.), which shows the age periods at which arrest most commonly took place.

TABLE VIII., *showing the Age Periods at which Arrest took place in 86 Cases.*

Total	86	

From these tables it is obvious that the decade 16 to 25 presents the greatest number of arrests; in other words, more arrests are likely to take place during the latter part of that decade, in the earlier part of which the onset of true epilepsy is most common—that is to say, the quinquennial period 16 to 20, in which the disease most usually declares itself, is succeeded by the quinquennial period 21 to 25, in which arrest is most frequent. This observation would corroborate the interpretation put upon the figures given in Tables VI. and VII., from which it is clear that epileptic fits are more prone to arrest during the first three or five years following their onset.

4. *The frequency of the seizures.*—The relative or average frequency of the attacks has an important bearing upon the prognostic outlook, as will be readily seen from Table IX.

The general conclusion may be drawn that the longer the interval between the attacks the greater the prospect of arrest or improvement. Very infrequent attacks are eminently favourable. Attacks which occur every three or four months, or once or twice a year, are—within certain

---

[10] Aphorisms, Section 5, No. vii. The aphorism is rendered in the Sydenham Society's translation, vol. ii., p. 738, as follows: "Those cases of epilepsy which come on before puberty may undergo a change, but those which come on after 25 years of age for the most part terminate in death."

TABLE IX., *giving the Percentage Frequency of the Attacks.*

Frequency.	Arrests. Per cent.	Improved. Per cent.	Confirmed. Per cent.	Total cases.
Daily (1 or more) ...	—	42·5	57·5	40
Weekly (1 or 2) ...	12·5	23·9	63·5	96
Monthly (1 or 2) ...	22·9	31·2	45·8	96
Quarterly (1 or 2) ...	36·9	24·6	38·4	65
Yearly (1 or 2)... ...	42·1	47·3	10·5	19
Total	—	—	—	316

limits and when considered in association with the points already mentioned in previous paragraphs—of more satisfactory prognostic importance than those which may be counted by the month, the week, or the day. The greatest percentage of confirmed cases and the smallest percentage of arrested cases are seen from the above table to occur in those epileptics who are subject to daily and weekly attacks, and the converse also holds good in that the smallest percentage of confirmed and the highest of arrested cases are found amongst those epileptics whose fits occur so infrequently as once or twice a year.

5. *The character and time of the seizures.*—The kind of attack to some extent modifies the prognosis. It is a matter of common knowledge that the major attacks are more readily influenced by drugs than the minor seizures. Owing to the incompleteness of the notes in describing the exact character of the fits it has been found impossible to construct a table of any real value, but so far as information has been supplied it is clear that the greatest percentage of arrests is to be found in cases of grand mal (49 per cent. out of a total of 96 cases); then follow the cases of combined grand and petit mal (35 per cent. out of a total of 56 cases); and lastly, petit mal occurring alone (26 per cent. out of a total of 15 cases). So also with regard to the time-incidence of the seizures. Those occurring by day only—including in this the very common early morning seizure—give a greater percentage of arrests (51·9 per cent. out of a total of 52 cases) than those occurring only during sleep (34 per cent. out of a total of 35 cases). Combined day and night attacks give also an arrest percentage of 34 per cent. out of a total of 35 cases.

6. *The influence of marriage.*—There would appear to be no real foundation for the popular belief that marriage predisposes towards cure, or even amelioration, of epileptic seizures. On the contrary, the consequences of matrimony tend to the production of circumstances distinctly unfavourable to the arrest or alleviation of the disease. Of 13 cases in which the disease was specially observed in its relation to marriage (all being women), five stated that they observed no change at all either in the frequency or the character of their fits; five appear to have slightly improved, in one of whom the improvement was only temporary; of the remaining three, one had her first seizure on the night of her marriage, another developed epilepsy seven months after marriage, while the third case seems to have been distinctly affected for the worse by marriage. These observations are in general harmony with what has been stated by other writers—namely, that there is no constancy in the influence of marriage upon the seizures.[11] The influence of marriage upon the transmission of the disease is a subject which scarcely comes within the scope of this paper, but some facts bearing upon it are incidentally mentioned and will be here briefly stated.

CASE 3.—A married woman, suffering from epilepsy, whose maternal grandfather had fits, bore six children, all of whom died from convulsions in infancy.

CASE 4.—Two epileptics, husband and wife, had six children. Three daughters and a son were well and without fits. Two other daughters, aged 16 and 18 years, developed fits when they were respectively 13 and 14 years old.

CASE 5.—A married epileptic woman, without any known heredity to the disease, had ten children, the eldest of whom was 37 and the youngest 20 years old. None of them had convulsions or fits.

CASE 6.—A married epileptic woman, whose two brothers also had fits, had a daughter who was also an epileptic.

CASE 7.—An epileptic man, without any known heredity, had ten children, the youngest of whom was 36 years of age. None of them had fits.

CASE 8.—An epileptic man without heredity, who had fits from 16 to 69 years of age, had two children, neither of whom had fits.

CASE 9.—A married epileptic woman had two children without fits, but both of them had an attack of chorea.

The above form only a small number of cases, but one fact stands out—namely, that of the three parents in whose family there was no known history of epilepsy, epileptic fits had not appeared in the children; that in the two cases in which the disease was obviously hereditary fits or convulsions were present in the offspring; and that in the case in which both parents were epileptic two out of six children developed epilepsy.

7. *The influence of pregnancy, parturition, and the puerperium.*—The influence of pregnancy has been noted in 20 cases. Of these, nine were free from seizures during this period, one patient stating that her longest free intervals occurred when she was in this condition. Of the remainder, seven were invariably worse when pregnant, two had fits only at or about the time of quickening, and one never observed any difference either in the frequency or character of the fits. In another case, in which the fits were arrested by bromides for a long time, an intercurrent pregnancy and subsequent puerperium intervened without any symptoms of epileptic seizures. It may therefore be concluded that gestation has little, if any, influence upon the disease. At the best there may only be a temporary respite; but pregnancy is the forerunner of the *puerperium*, a period which is especially prone to epileptic attacks. Of 19 cases in which this state was noted all gave a history of one or more severe attacks within a short period, usually a few days after the birth of the child. In two of the cases the onset of the disease was observed after the birth of the first baby and in one after the birth of the fourth child. *Lactation* would seem in some cases to be peculiarly favourable for the occurrence of fits. In one case the fits only came on during the period of suckling and this happened after three successive pregnancies. On weaning the fits disappeared. In a second case the first fit arose while nursing the first baby four months after confinement. From the above facts it would appear as if there were three periods when epileptic fits were prone to develop—at quickening, during the first few days of the puerperium, and during lactation.

8. *The influence of sex.*—Sex plays little part in the prognosis of epilepsy. The following table (Table X.) will show the percentage of arrested, improved, and confirmed cases in this relation. From this it is seen that rather more males show arrest of the seizures, but at the same time this sex gives a greater percentage of confirmed cases.

TABLE X., *showing the Sex Percentage of Arrested, Improved, and Confirmed Cases.*

	Arrests. Per cent.	Improved Per cent.	Confirmed. Per cent.	Total cases.
Males...	26	22	51	179
Females	20	34	44	187
Total	—	—	—	366

These results are in harmony with those of several previous observers (Reynolds, Gowers, and others), but are in opposition to the statement of Herpin.

9 *The influence of the catamenia.*—Menstruation would appear to exert little influence upon the prognosis of epilepsy. The popular belief that the satisfactory and regular establishment of this function will arrest or ameliorate the disease has no scientific basis. The onset of epileptic fits during puberty is not uncommonly accompanied by irregularity in the menstrual periods, but it is rare to find any amelioration in the frequency or severity of the attacks when the period becomes regularly established. It will be seen that amenorrhœa induced physiologically by pregnancy may or may not have any beneficial effect. There were some cases also in which the fits became arrested at or about the climacteric period, but the evidence is too small to state definitely that this is an epoch at

---

[11] On this point see some statistics collected by A. Hughes Bennett, Brit. Med. Jour., March, 1879.

which spontaneous arrest may be expected. A reference to Table VIII. will show that 8 per cent. of the cases were arrested between the ages of 41 and 45 years, but only three of these were women. There was one patient, however, who seemed to lose her fits when she was subject to amenorrhœa, from which she occasionally suffered for prolonged periods. During these periods she was invariably free from attacks, which reappeared when the catamenia were established.

10. *The influence of accidental factors.*—A few words may be said upon the influence of accidental factors in relation to the production of epileptic fits. In two cases an intercurrent attack of pneumonia was noted. In one, although several seizures occurred during the course of the pulmonary inflammation, a respite from fits was subsequently obtained lasting for several months. In another, during a long spell of freedom from fits an attack of pneumonia brought about a temporary return of the seizures. In another patient an attack of chorea was followed by a year's freedom from fits. In another an attack of scarlet fever greatly increased the number and severity of the epileptic seizures. In another case a long interval of freedom was broken by the patient receiving a severe blow upon the head. In a case of epilepsy the gradual onset of paralysis agitans made no difference to the pre-existing disease. As a rule an attack of acute febrile disorder gives a subsequent temporary respite from fits, with the exception of scarlet fever, a fact which has also been noted by Gowers. On the other hand, the *onset* of an acute pneumonia may be accompanied by severe seizures or by a temporary relapse during a remission from fits. Injuries, such as blows upon the head, aggravate the disease, an observation which is in harmony with what occurs in other chronic nervous disorders. No prolonged relief from epileptic fits can therefore be predicted after the occurrence of an acute inflammatory disorder.

Types of epilepsy.—Even a brief acquaintance with epileptics will show that there is a marked periodicity in the occurrence of the seizures, which is highly characteristic of the disease. The intervals are of varying duration—a day, a week, two weeks, a month, two or three months, a year, or longer. These intervals are, however, not absolutely regular, considerable variability and irregularity being observed on charts specially kept for recording the time periodicity of epileptic fits. Such, indeed, is the common incidence of attacks; but attention has been directed by Biro[12] to certain types of cases which have apparently some bearing on prognosis. These types have been called "increasing" or "decreasing," and some examples will be given to illustrate their characteristics. The types may be described either by the number of fits per month or per year, in increasing or decreasing numbers, or by the number of years or months intervening between the seizures. The following cases may be taken as illustrative of the types. Cases 10, 11, and 12 are of the increasing type; Cases 13, 14, and 15 are of the decreasing type; and Cases 16 and 17 are blended increasing and decreasing types.

CASE 10.—In this patient fits commenced at 15 years of age. Three fits occurred in the first year (without treatment); four in the second year (under bromides); nine in the third year (under bromides); and ten in the fourth year (under bromides) After this the patient ceased attending. It is seen that the fits went on increasing, notwithstanding the continuance of treatment.

CASE 11.—This patient had the first fit when five years of age, the second when 11, the third when 19, the fourth when 20, and the fifth and sixth when 21. He was then put under bromide treatment and has had no fits for eight years.

CASE 12.—In this patient fits commenced at [illegible] years of age. [illegible] about [illegible] fit in December, 1897; interval of two years; two fits in January, 1900; interval of one year; two fits in 1901; three fits in 1902; since which date there has been no further observation.

CASE 13.—In this patient fits commenced at 39 years of age. During the first year of bromide treatment the patient had several attacks; the second year, four; the third year, one; the fourth year, two; the fifth year, one attack; and the sixth, seventh, eighth, and ninth years, none.

CASE 14.—In this patient fits commenced at 21 years of age. During the first year of treatment the patient had 12 or more fits; the second year, 12; the third year, 12; the fourth year, three; the fifth year, four; the sixth year, two; and the seventh, eighth, and ninth years, none.

CASE 15.—This patient came under treatment at 19 years of age, having a fit every two or three weeks. During the first year of treatment he had about 12 fits; the second year, several; the third year, eight; the fourth year, four; the fifth year, one fit; and the sixth year, none.

The two types, as above described, may, upon the other hand, be found blended in the same case; for example, one of increasing character may as the result of treatment be changed into the decreasing type and of this description are the two following cases.

CASE 16.—In this patient the first fit occurred at 12 years of age, the second after eight years' interval, the third after five, the fourth after five, the fifth after two, and a batch of three fits after three. He then came under regular bromide treatment and had two fits in the next year, three in each of the two following years, five in the next year, one fit a year later, and none in the next three years.

CASE 17.—When aged 25 years, in 1882, this patient had his first fit, in 1884 his second, from 1884 to 1887 he was free from attacks, from 1887 to 1890 he had several, in 1891 four, in 1892 11, in 1893-94 eight, in 1895 six, in 1896 three, in 1897-98 none, in 1899 one very slight, and in 1900-01 none.

The above-recorded cases, although symbolic of the types referred to, are rarely met in such purity. Their prognostic importance may be briefly stated as follows: (1) In the increasing type, as shown in Cases 10 and 12, the fits through a natural inclination to [illegible] spite of treatment. On [illegible] unfavourable for arrest, [illegible] type is more commonly induced by treatment and if clearly established has a favourable outlook.

Long remissions in epilepsy.—It is well known that remissions are a frequent, if not a characteristic, feature of this disease. The common remission which takes place during childhood in those patients whose fits commence in infancy, then cease for a time and recur at or about the time of puberty, is one of the most remarkable features of this disorder. An interval of several years not infrequently occurs between the first and second attacks, while numerous instances may be cited in which periods of five, ten, or 15 years have been known to elapse between epileptic seizures. Wharton Sinkler[13] records a remission of 29 years in one of his cases. An examination of the present series reveals a number of instances in which remissions have been observed and which have persisted for a number of years, but which have been succeeded by a return of the characteristic seizures. In the cases in which *arrest* is stated to have occurred, freedom from fits was noted over periods varying from two to 25 years (these have not been included in the present table), but in Table XI. will be found the list of cases which show *remissions* lasting for more than two years, with subsequent relapse.

TABLE XI., *showing the Cases of Remission and their Duration.*

"	"	15	"	"	1 "

[illegible] the remission occurred during the adminis-[illegible] of them the fits returned, not-[illegible] the drug. [illegible] ion of such cases that most information may be gleaned with reference to the possibility of a cure of epilepsy it will be instructive to study some of them with greater detail. In one case there were two periods of remission, one lasting for three and a half years without any remedies having been given and the other for four years under bromide treatment. The fits eventually recurred with symptoms of automatism and violence. In another an interval of six years of freedom was succeeded by a return of fits in increasing frequency. In a third there were two remissions, one of three years and a second of five years, to be followed by fits occurring about every month. In another an apparent arrest for seven years was broken by two fits during an attack of acute pneumonia. In the patient remission of whose seizures lasted for 15 years the relapse was characterised by the occurrence of petit mal. It should be pointed out that in all the above cases the disease had been fully established for some years and that the intervals therefore do not correspond to the prolonged periods sometimes found between the first and second fits to which reference has already been made. Two points especially call for notice in this connexion: on the one hand, long remissions may occur under the administration of bromides to be followed by a relapse when the drug is omitted; and on the other hand, a remission of long duration may be broken by accidental circumstances, such as a blow on the head, a fall, childbirth, or an acute inflammatory disorder. Hence it is apparent that long periods of arrest, though as a rule indicating a favourable prognosis, are not synonymous with a cure of the disease. The question may therefore now be asked—

---

[12] Biro: Deutsche Zeitschrift für Nervenheilkunde, vol. xxiii., p. 40.

[13] Wharton Sinkler: Journal of Nervous and Mental Disease, [illegible], p. 601.

Is there a cure of epilepsy?—This question may in general terms be answered in the affirmative. Two cases (Cases 1 and 2) have been already mentioned in which this occurred and not a few instances may be gathered from amongst epileptics and neurasthenics who state that they suffered from fits in earlier years, and if the later histories of epileptics could be traced many more instances might no doubt be added. Although writers are generally agreed as to a cure of epilepsy there is a less general consensus of opinion as to what is the definition of a cure—that is to say, after what period of arrest a "cure" may be said to have taken place.[14] Before attempting to answer this question it is necessary to refer again to a few points to which attention has already been directed. With this object in view, Tables II. and XI, dealing especially with the cases of arrest and long remission, are blended and reproduced side by side in Table XII., which gives the number and duration of the cases of arrest and remission:—

TABLE XII., *giving the Cases of Arrest and Remission with the Duration.*

86	Total ...	13						

The arrest column shows that the greater number of the cases (71 out of a total of 86) were observed over a period of from two to nine years during which no fits occurred; while of the cases of remission, although four showed an arrest of from four to five years, in five a relapse occurred up to eight years, after which time only one was found to relapse. When these results are compared in conjunction with those of Wharton Sinkler, who observed only four cases of relapse out of a total of 24 after nine years' remission, I have thought it *unsafe to regard as cured any case of epilepsy in which the seizures have been in abeyance for a period of less than nine years* after the disease has become satisfactorily established. This provision is made in order to eliminate all those cases of remission during childhood which are known to last for seven, eight, or nine years and also those cases in which long intervals elapse between the first and second or second and third fits at the commencement of the disease. In order to obtain the percentage of cures in the present series those cases only have been taken which were under observation for a period of at least nine years. They form a total of 147 of which 15 were arrested for nine or more years (*vide* Table II.), *giving a percentage of 10 2 cures.*[15] Taking the series of cases with long remission recorded in this paper along with those of Sinkler it is found that a few still remain in which relapse occurred after the nine years' limit—viz., four by Sinkler and one by myself. Therefore, although it may be laid down as a general rule that a cure of epilepsy has been established after an arrest of nine years, the fact must be borne in mind that a very small percentage of cases do relapse after that period. While discussing the cure of epilepsy, a point of practical importance which should not be overlooked is that those who have been cured of their seizures not infrequently show various mental peculiarities such as impairment of memory, irritability of temper, headache, and a tendency towards neurasthenic symptoms.

The curable cases of epilepsy.—Although in the present series of cases there is no definite information as to the mental condition of the patients, clinical experience and observation show that many cases of epilepsy may exist for prolonged periods without any material mental impairment. Such cases would appear to belong to what may be termed a curable type of epilepsy. A special investigation has therefore been made into the duration of the disease before regular treatment was established in the 86 cases in which arrest took place From this it is seen that of 44 cases in which arrest took place during the first year of treatment the disease had been in existence during periods varying from one to 35 years, with an average duration of seven years. This investigation also brought forward a point of great importance—namely, that if any given case of epilepsy is capable of amelioration by treatment a satisfactory response will be shortly apparent, as Table XIII. shows.

TABLE XIII., *showing the Influence of Bromide Treatment upon 86 Cases of Arrested Epilepsy.*

Arrest under 1 year's treatment	44	cases,	or 51·7 per cent.

Total	86		

From Table XIII. it is obvious that over 50 per cent. of the cases in which arrest took place yielded to treatment within the first year of regular bromide administration.

SUMMARY AND CONCLUSIONS.

1. A total of 366 cases, chiefly derived from the out-patient records of the National Hospital for the Paralysed and Epileptic, has been used for the investigation.

2. Only cases of genuine idiopathic epilepsy which had been under constant observation and treatment for a period of at least two years have been taken. All cases of symptomatic epilepsy, or cases otherwise complicated, were as far as possible eliminated.

3 The cases have been divided into three series, according as they have responded, successfully or otherwise, to treatment—arrested, improved, and confirmed cases. The influence of the various conditions modifying prognosis has been mentioned in detail, the results of the observations being stated in percentages.

4. A family history of epilepsy will be found more frequently amongst those who have become confirmed epileptics, but a hereditary history of epilepsy does not necessarily militate against the prospects of arrest or improvement of the disease in any given case.

5. The age at the onset of the disease has an especial bearing upon the prognosis. The most unsatisfactory cases are those in which the disease commences under ten years of age; they show the smallest percentage of recoveries and the largest of confirmed cases. If the disease arises between 15 and 20 years of age an almost equal percentage of arrested and confirmed cases may be expected. The greatest percentage of confirmed cases is found amongst those in whom the disease begins between 25 and 35 years of age, from which time onwards there is a steady increase in the expectations of arrest and diminution in the number which become confirmed.

6. The duration of the malady influences the prognosis to the extent that arrest or improvement is much more likely during the first five than during the second five years. Cases, however, may be arrested even after a duration of from 20 to 30 years.

7. The greatest percentage of confirmed and the lowest percentage of arrested cases occur in those epileptics who

---

[14] Reynolds defined a cure as perfect restoration to health for at least four years, and at most eight years, after arrest of the fits.

[15] There is a striking harmony between these results and the percentage of cures obtained by Reynolds (10 per cent. with a basis of from four to eight years) and Habermaas (10 3 per cent. with a five to ten years' basis).

are subject to daily or weekly attacks, while conversely the smallest percentages of confirmed and the highest of arrested cases occur in those whose fits are as infrequent as once or twice a year.

8. The character of the seizures influences the prognosis to the extent that the major attacks are the most tractable; then follow combined major and minor seizures; and lastly, the minor attacks occurring alone.

9. Marriage exerts little, if any, influence upon epileptic fits. Some patients are relieved and others are made worse. In the majority of cases the disease remains unaffected.

10. Pregnancy has little influence upon the seizures; at the best there may be only a temporary respite. On the other hand the puerperium would seem to be especially favourable for the recurrence of fits; while lactation also is not without an exciting influence in their production

[illegible] of epileptic fits is an irregular [illegible] es, however, which have been [illegible] or "decreasing," according as the fits increase or decrease in number in a definite period of time or in which there is a shortening or lengthening of the intervals between the fits. A case of increasing type may by treatment be converted into one of the decreasing variety.

12. Long remissions, induced either by successful treatment or from spontaneous cessation of the fits, sometimes lasting for several years are not unusual in epilepsy; they are of favourable prognostic value but are not synonymous with a cure of the disease.

13 From the collected statistics *a period of remission for at least nine years has been fixed as the basis upon which a cure of epilepsy may be established. With this definition of a cure I regard 10 2 per cent. of epileptics as curable.*

14. There are some cases of epilepsy which may be regarded as belonging to a curable type of the disease. These present little or no mental impairment, notwithstanding that fits may have existed for a long period In the cases in which arrest took place cessation of the fits occurred within the first year of continuous treatment in over 50 per cent.

MALARIA AS SEEN IN THE ANDAMANS PENAL SETTLEMENT.

BY ERNEST EDWIN WATERS, M.B., C.M. EDIN.,
CAPTAIN, I.M.S.; OFFICIATING SUPERINTENDING MEDICAL OFFICER, PORT BLAIR.

MALARIA is the disease that causes by far the greatest amount of sickness in the Andamans penal settlement and which consequently causes a serious disorganisation of the labour supply and a heavy financial loss to the administration. In 1902 there were nearly 14,000 admissions from malaria and though only 57 deaths were directly attributed to this disease, yet I am convinced that many patients who died from other diseases had their constitutions undermined by previous malarial attacks. In other words, a healthy man has strong resisting powers to the bacilli of dysentery or tuberculosis, but once his vitality is lowered by malaria he falls an easy prey to these complaints. The tax of malarial fever is a very heavy one; taking 14 days as the average period for which fever cases are non effective, malaria alone in 1902 accounted for 196,000 labour units (one man for one day) or, at four annas per day, for 49 000 rupees. This represents the labour of 2000 men for 98 days. And a [illegible]
establi [illegible]

On [illegible] that in 1902 the least malarial month was February, with seven inches of rain, that the admissions increased slightly in March, much increased in April, further increased in May, till they reached a maximum in June. In July there was in nearly all districts a decline in the malaria more or less marked, whilst in August and September, the two wettest months of the year, the admissions *for fever sharply* declined. These statements also apply for the two previous unhealthy years 1900 and 1901, but more especially to the larger stations and districts. Ross Jail and the Female Jail show variations and do not conform to this Table I. shows precisely the proportion of the monthly malarial admissions in the various areas and the rainfall from January, 1902, to March, 1903, inclusive. The rainfall shown is the average of the whole settlement. In 1902 Ross was the wettest station.

TABLE I.—*Showing the Number of Admissions for Malaria into the Hospitals and the Average Rainfall from January, 1902, to March, 1903, inclusive*

March	*Nil.*	67	88	64	33	310	213

The approximate strengths in the various hospitals during the period mentioned were as follows: Ross, 700; Aberdeen, 2200; Haddo, 1800; the Female Jail, 400; Wimberley Ganj, 2350; and in the Southern District, 3500.

There are two methods in which we may attempt to account for the prevalence of malaria: (1) the purely mosquito theory; and (2) the relapse or recrudescence theory.

I.—THE PURELY MOSQUITO THEORY.

This would require infection from a specific anopheles to account for every attack of malaria, and the malarial admission rate should be coincident with a marked increase in mosquitoes or at least with more favourable conditions for their existence. Now, our malaria begins in April, the hottest and one of the driest months It increases and [illegible]

which flourishes in the hot month of April and the wet ones of May and June, suddenly dying off in July and subsequent months, although these months, from conditions of temperature and moisture, would appear to be equally suitable for their development. More than this, the number of cases of malaria from which the mosquitoes may become infected is much greater in May and June and consequently the number of infected and dangerous mosquitoes should be much larger With more infected mosquitoes the malaria rate should rise, but it undoubtedly falls. (It has been suggested to me that the mosquitoes themselves become so ill from malarial poisoning that they, too, die off. This theory is ingenious but it is hardly practicable to investigate it.) Also, it may be that in July other mosquito eating insects and animals appear who prey upon the culicidæ and so enormously reduce their numbers.

If we can exclude mosquitoes, does malaria diminish? It does, most decidedly. For the past 15 months careful experiments have been carried out in the Female Jail, one of the most unhealthy and malarious units in the settlement. This experiment was initiated by Major Anderson, I.M.S., and has since been extended by me.

37 women selected from all classes were placed under mosquito curtains, going under them at dusk and coming out in the morning. Their occupation, health, and food in no way differed from any other section of the jail. The remainder of the jail population was divided into two classes. To one class 20 grains of quinine were given in two successive days; to the other no prophylactic issue was made. The effect was most marked. In Class A, in which the women slept under mosquito nets, there were 1007 admissions per 1000; in Class B, who received quinine, the admissions were 2421 per 1000; and in Class C, who received no quinine, they were 4177 per 1000. I believe that the figures would have been better in Class A but for an unfortunate case of chicken-pox in one of the women which necessitated a change in the inhabitants of a second net which had just been occupied. These figures go to show that under conditions prevailing in the Female Jail the exclusion of mosquitoes is an effectual and inexpensive method of reducing malaria.

II.—The Relapse or Recrudescence Theory of Malaria.

This theory is somewhat heterodox nowadays but it has some grounds for consideration. To begin with, practically every native who comes to the Andamans has suffered from malaria in his youth and probably has had several attacks of fever. He has not become immune or he would not suffer from malaria or fever. The malarial parasites are supposed to be locked up in the spleen and under favourable conditions will be eventually destroyed there. But it is a matter of common knowledge that in the case of a person who has once suffered from malaria a chill, over-exposure, &c., will induce a fresh attack, even years after the original infection, and that a malarial subject should avoid circumstances where he is likely to be so exposed. Now, as I have said above, most natives have suffered from malaria and on arrival here as prisoners they are subject to new and trying conditions. The climate, water, and food are strange to them, they are worked hard, and they are constantly exposed to sun, rain, and wind. *Differing from free men they cannot, if feeling only slightly unwell, leave work for a day or two, change their food, or take life a little easily.* They must either work on or go sick to hospital, with the possibility of not being admitted and the risk of punishment. Our hospital figures substantiate this theory. Well-cleared, established stations like Aberdeen, Haddo, and Phœnix Bay are less malarial than out-stations like Goplakabang, but even in the healthy stations it is the men doing hard outdoor work who furnish the bulk of the malarial cases. True, it is these men who have the most inducement to come to hospital; but latterly all our cases of malaria have been examined microscopically and I have yet to find a malingerer who is competent to produce pigmented crescents at will or to arrange for a suitable increase in his large mononuclear leucocytes. It appears to me that the convict may at times derive his fever from the bite of infected mosquitoes but that he may also have a relapse from a previous attack through exposure, overwork, or some cause lowering his vitality. Again, while a healthy, well-nourished man may only suffer slightly from fever after an infected bite, it is obvious that a weakly, chilled, tired man whose powers of resistance are much lowered would in all probability suffer to a much greater or more serious extent.

This question is admirably worked out by Attilio Caccini[1] of Rome. He gives specific instances (with detailed examinations of cases) where fever has re-appeared within 48 hours of exposure to damp and cold, even in patients who were taking quinine regularly at the time of exposure. He further proves "that in patients not treated with quinine, in whom the primary malarial infection has exhausted itself, the attack recurring after a long period always comes on after the intervention of one of these recognised determining causes." In these cases parasites rapidly reappear in the blood. He says, further: "The attack recurring after a long interval exactly resembles true first infection—that is, the paroxysms of fever may be more or less regular; attacks may or may not occur at long or short intervals and they react equally against the quinine treatment. But whereas regular systematic treatment prevents attacks recurring at short intervals it does not prevent those recurring at long intervals, which come on after a space of time which may reach 12 months of apyrexia. The attack always occurs upon the intervention of any of the organically debilitating causes mentioned. Thus with patients treated with quinine and divided into categories according to the method of treatment every category shows the same percentage of attacks occurring at long intervals. In every case the attack followed upon the intervention of one of the debilitating causes above noted. Any patient guarding against debilitating accidents and observing a regular diet may remain free from attacks of fever for a long while (from six to seven months) but suffers a relapse after that time upon exposure to cold, fatigue, wounds, or illness."

Now these statements correspond with our experience here. We know that exceptionally hard work will send up the fever admissions from the men exposed to it, especially when proper precautions are not taken. On Ross Island in the period from December to March there is usually a strong cool wind blowing and it is to this that the population ascribe their fever. They say beforehand that when this wind begins they get fever, and they certainly do. I do not think that at that time there were any anopheles mosquitoes on the island—certainly one could never catch them—and even culices were very rare. The wind came directly from the north-east over some hundreds of miles of sea, so that the chances of infected mosquitoes being carried in may be dismissed.

The probability is that both these theories are true and that direct infection from the mosquito and relapses due to exposure together and unitedly account for the malaria as seen here.

The Means of Diminishing Malaria.[2]

Any measures that will diminish the heavy malarial sick-rate are naturally of the greatest value and much attention has been paid to this question during the past year. So far as our present knowledge goes three, or possibly four, methods are supposed or are likely to be efficacious (always remembering that we are dealing with a malaria-infected population). These are: (1) the destruction of all anopheles mosquitoes; (2) the prevention of infection of, and by, anopheles mosquitoes by means of nets or combustible pastilles; (3) the dosage of the whole population with quinine to an effective extent; and (4) the keeping of the population "fit" or in such a good state of general health that relapses or recrudescences are unlikely.

1. *The destruction of all anopheles mosquitoes.*—This I have no hesitation in saying under local conditions is impossible. The large area of the settlement, the dense vegetation, the heavy rainfall and consequent swamps all make such a task impossible of fulfilment. It may be done over comparatively small areas and in the older stations, but to do it over the 100 and odd square miles within the settlement boundaries is not practicable. But even on a small scale much good may be done and I propose to describe in detail the results of the efforts made. The first attempts were made on Viper, a small island accommodating about 1000 convicts and some 250 troops and police. This island has no streams; its water-supply is from collected rain water, one or two wells, and from a daily ration brought from another station. The island is thoroughly cleared and well drained. Like all other stations the buildings are of wood and as a protection against fire there are wooden fire barrels distributed round all the houses and barracks. These fire barrels were the main sources from which the mosquitoes came and early in the year every barrel swarmed with larvæ and mosquito eggs could always be found. Generally these larvæ and eggs were of the culex variety, but occasionally anopheletes were discovered. The work of getting rid of mosquitoes was commenced in June with a few convalescents who were instructed to keep these barrels clean and to pick up cocoanut shells, &c. The results were excellent so far as the number of mosquitoes were concerned. On every hand one got the same response to inquiries, from officials and convicts alike. The mosquitoes were much less numerous, nets were no longer a necessity, and life was rendered much more tolerable in consequence. At the same time experiments were made with combustible pastilles, so evil-smelling as to be calculated to drive out the mosquitoes from any building in which they were burnt. These were

---

[1] Journal of Tropical Medicine, May and June, 1902.

[2] Vide Ross's report on Malaria at Ismailia, 1903.

made of sulphur, charcoal, and saltpetre but were not satisfactory. They were expensive (the cost to burn them twice weekly throughout the settlement at the scale of 1 per 1000 cubic feet would have been about 10,000 rupees) and they were only temporarily effectual. The general opinion was that so long as they were burning neither man nor mosquito could exist within their range but that as soon as they had burnt out sufficiently to permit the inhabitants to return the mosquitoes returned also. Following the small Viper experiment and other small experiments elsewhere a more thorough trial was decided on. In November the Chief Commissioner issued orders forming mosquito brigades in every station and these commenced operations on Dec. 15th. Information and literature, including Ross's book, had previously been widely circulated and the petty officers in charge of the gangs were instructed in their duties. The men of the brigades, numbering in all nearly 200, were equipped with carts, tools, and dippers for searching purposes. Careful arrangements were made to check the exact sleeping places and occupations of all men reporting sick and the blood of every fever case was examined microscopically, often more than once.

In some respects the results of these special gangs have been excellent. Mosquitoes everywhere have enormously decreased—in fact, in many places a mosquito is quite a rarity and as such is immediately noticed. The exact prevalence in bungalows appears to depend on the interest and enthusiasm of the occupants. Many residents have assured me that they can now sleep without nets or punkahs and the convicts all tell me that mosquitoes have much diminished. Besides this the general sanitation of the settlement has much improved. Drains have been cleared, puddles filled, rubbish removed, and undergrowth cut back to a considerable distance. The improvement in the general cleanliness is most marked and in this respect alone the mosquito gangs have done much good. But when we examine the effect of these measures on the malarial admissions we do not obtain such encouraging or consistent results. The results from the principal stations and districts are as follows for the three months during which the brigades have been working (Table II.).

TABLE II.—*Ross Island.*

Period.	Approximate strength.	Admissions for fever.
December, January, and March, 1899-1900	660	43
,, ,, ,, 1900-01	693	82
,, ,, ,, 1901-02	735	48
,, ,, ,, 1902-03	718	203

Of this season's admissions, mullahs furnished 67 and sweepers 25. 49 admissions came from No 1 barrack and 29 from each of the others. Government House, the senior medical officer's bungalow, and the mess, which are close to one another, each had ten fever admissions, whilst two other bungalows, which are side by side gave 13 and 12 admissions respectively. No other house had anything approaching this number. These cases are very difficult to explain on the purely mosquito theory. In the patients (boatmen) from the senior medical officer's bungalow distinct parasites were found and in two cases crescents; at that time of the year it was impossible to discover an anopheles on Ross Island. The patients generally and many of the residents, too, ascribed their fever to the onset of the north-east monsoon which, they say, chilled them and gave them fever. On the other hand, both the areas above named are thickly covered with vegetation which gives good mosquito cover.

TABLE III.—*Female Jail.*

Period.	Approximate strength.	Admissions for fever.
Three months in 1899-1900	359	140
,, ,, ,, 1900-01	379	109
,, ,, ,, 1901-02	406	80
,, ,, ,, 1902-03	401	163

The results shown by Table III are similarly disappointing. It is easy to explain why the Female Jail should be malarious, but it is not easy to explain why it should have been more malarious this year than usual, when stringent sanitary precautions were exercised and when half the inhabitants were taking 20 grains of quinine twice daily.

At Ross hospital the blood of every patient coming to hospital was examined for malaria parasites, whatever his disease may have been. In all, 527 patients[3] were examined and parasites were found in 136 cases. The analyses showed intracellular hyaline, 49 times; intracellular pigmented, 36; extracellular forms, 20; and crescents, 31. There were also combinations of these varieties. In many cases crescents were found in enormous numbers, as many as 180 being counted in a single slide. In other cases crescents abounded in the blood of men feeling perfectly well, having normal temperatures, and who were anxious to go out of the hospital.

TABLE IV.—*Aberdeen.*

Period.	Admissions for malaria.
December to March, 1899-1900	312
,, ,, 1900-01	234
,, ,, 1901-02	70
,, ,, 1902-03	215

At Aberdeen Hospital, too (Table IV.), careful blood examinations were made, but the results are included with those of Haddo hospital.

At the Female Jail the malaria admissions for January were 66; for February, 49; and for March, 33. Microscopic examination of the blood in the 212 cases which were examined (being all the admissions) revealed parasites in 125 cases, of the following varieties: hyaline intracellular, 47; intracellular pigmented, 36; extracellular pigmented, 26; and crescents, 16.

TABLE V.—*Haddo, Chatham, and Phœnix Bay.*

Period.	Haddo fever admissions.	Chatham fever admissions.	Phœnix Bay fever admissions.
1899-1900	152	154	186
1900-01	69	54	92
1901-02	78	33	58
1902-03	49	28	49

In Haddo, Chatham, and Phœnix Bay (Table V.) the results are favourable; everywhere there were fewer cases, although in 1902 the population tended to increase steadily. Possibly the inhabitants of these stations are less exposed in the cold season to changes of temperature than most other men and consequently are more likely to benefit from anti-mosquito efforts. As in other cases, careful blood examinations were always made. 194 fever cases were examined and parasites were found in 173 cases of the following varieties: intracellular hyaline, 101; intracellular pigmented, 23; intracellular ring forms, 21; extracellular pigmented, 10; crescents, 10; segmenting forms, 6; and flagella 2 This blood examination was carried out by Dr. Sanyal who ascribes the high parasite rate to the facts that only "fever" cases are included, that there was no prophylactic issue of quinine going on, and that no quinine was given to the patients until the blood examination had been made and the diagnosis checked.

SOUTHERN DISTRICT.

It is in an unhealthy area such as this that the mosquito brigade work is of special interest Attention was specially directed to Viper, Namunaghar, Dundas Point, and Minnie Bay (Table VI.).

TABLE VI.—*Showing Number of Cases in Southern District.*

Period.	Viper.		Namunaghar.		Dundas Point.		Minnie Bay.	
	Average for 3 years.	1902-1903	Average for 3 years.	1902-1903	Average for 3 years.	1902-1903	Average for 3 years	1902-1903
December	35	76	101	61	49	25	5	9
January	40	53	75	41	33	35	23	12
February	52	64	53	27	43	31	43	19

---

[3] These figures include sick from Aberdeen.

Of the 129 admissions from Namunaghar in the three months 83 came from one barrack—the temporary one—but the firewood cutters (who are always unhealthy) lived in this barrack. Altogether the blood of 592 fever cases was examined. In 289 of these malarial parasites were discovered.

TABLE VII.—*Wimberley Ganj Subdivision.*

Period.	Approximate strength.	Admissions.
1899-1900	1480	520
1900-01	1944	916
1901-02	2161	811
1902-03	2352	603

In Wimberley Ganj Subdivision, too (Table VII.), there is a decline in the admission rate as compared with previous years and that although the population of the subdivision has increased. In 1062 blood examinations made from October to February parasites were found in 892 cases, of the following varieties: extracellular hyaline, 851; extracellular, 19; and crescents, 22.

The above tables are, of course, but a summary of all the information which has been collected on this subject but which want of space prevent me from inserting. This account does not exhaust what has been done in the direction of mosquito brigades. In the villages, both ticket-of-leave and free, the system has also been inaugurated and men have been told off to attend to puddles, sanitation, and general cleanliness. The effect of this action is bound to be most marked.

I am indebted to Mr. Lowis, the subdivisional officer of Ross, for much assistance in connexion with the mosquito brigades and for the following information as to local varieties of the insect.

The commonest variety of mosquito in Port Blair is *Culex fatigans.* It is a house mosquito, breeding in any convenient collection of water and biting at all hours, but especially at night. The only other known variety of culex locally found is *Culex concolor*, a larger insect than *Culex fatigans* and possessing larvæ of cannabalistic habits. There is one other small culex found but it has not yet been identified. Of the subfamily stegomyia (Theobald) two species are found—namely, *Stegomyia fasciata* and *Stegomyia scutellaris.* Both are very common here, but they do not affect houses as much as the true culex. They breed usually in stagnant pools containing vegetable débris, such as hollows in trunks of trees. This species wanders further from its breeding-places than culex does and is often found where there is no possible breeding-place and where *Culex fatigans* disappears. Only one variety of anopheles is known here, the *Anopheles Rossii*, and that has been found only in two places. The breeding-place which this variety affected was a series of pits excavated during the building of a convict barrack. This variety was also discovered at Dundas Point. Except when these pits were in existence it was impossible to find any anopheles larvæ on Ross Island. Another mosquito of the subfamily panoplites has also been caught but only in small numbers. Of *corethra* three varieties were discovered, one of which breeds largely in the Ross drinking-water tank and is the only larva to be found there. These corethræ appear to have no biting apparatus and therefore can hardly be said to be carriers of infection. One variety has not hitherto been described and appears to be a new one discovered by Mr. Lowis.

On the whole, mosquito brigades are of distinct benefit; for some unexplained reason they have not succeeded this season in Ross and Aberdeen, but in the other districts the results are encouraging Undoubtedly the stations are much cleaner and the number of mosquitoes less, but the latter are far from being exterminated; they no longer flourish in the fire barrels or in the immediate vicinity of barracks, but except in very small or special areas or where there is enthusiastic European supervision these pests will remain and will continue to carry infection.

2 *The prevention of infection of, and by, anopheles mosquitoes by the use of nets or combustible pastilles.*—At first sight this appears to be the remedy offering the best prospects. We know that a net will keep off mosquitoes and we also know, from 15 months' steady observation in the Female Jail, that persons sleeping under a net have only one-fourth the risk of malaria that unprotected people have and when attacked with fever are a shorter time in hospital. The cost, too, of mosquito netting is comparatively little. Why not, then, introduce it? The great drawback to netting is its interference with ventilation. Even under an ordinary mosquito net the difference in the freshness of the air inside and outside is quite marked and this is equally the case with a larger net containing 20 or 30 people. The women in the jail complain much of the heat under the net and it is absolutely certain that if nets are to be taken into general use as malaria guards the amount of cubic space per head must be very considerably increased, for there is practically no movement of air through the meshes of a thick net. The question is of much importance owing to the prevalence of phthisis and one is confronted by two precisely opposite problems. To check malaria in this way one must put up nets to exclude mosquitoes and consequently seriously interfere with the air-supply. On the other hand, to check phthisis we must have better ventilation, more air, and more superficial space. Which is the better? I think the balance is in favour of more space and more air combined with measures to be presently discussed.

3. *The dosage of the whole population with quinine to an effective extent.*—This procedure is strongly recommended by many authorities, more especially by the Italian observers and by Koch. The theory is that the administration of one gramme of quinine daily for two successive days and the repetition of this every week will check the occurrence of malaria by inhibiting the growth of parasites. The local opinion is against this theory, but quinine had never been given in sufficiently large doses nor had the distribution been made on sufficiently systematic lines. Naturally, over a district comprising 130 square miles of country and populated by men of very varying occupations, who cannot always be caught at meal or other parades, the issue of quinine regularly is a very difficult matter. Major Anderson's experiments showed that small doses of quinine, such as from two and a half to five grains daily, had absolutely no effect on the malaria admissions of the Female Jail but that the effects of large doses were more favourable. Longer observation has confirmed this view. The administration of 20 grains of quinine twice weekly has halved the admissions for malaria but the remedy is not a specific. During the malarial outbreak last year I directed that a further experiment should be made at Bindrabun, probably the most malarious place in the settlement, but the results were most disappointing so far as this station goes. 120 men were taken and their names recorded. To the even numbers 20 grains of quinine were given on two successive days, to the odd numbers nothing. The results were as follows (Table VIII.):—

TABLE VIII.

—	June.		July.		August.	
	Quinine.	No quinine.	Quinine.	No quinine.	Quinine	No quinine.
Admissions.	42	42	31	33	21	22

The average stay in hospital for those men taking quinine was 5 56 days and for those taking no quinine 5·60 days. After August the special experiment was discontinued.

In June last an attempt was made to check the malaria by an issue of ten grains of quinine to every convict on two successive days, repeated weekly. With the help of the executive authorities diaries were arranged and parades were organised. Compounders accompanied by petty officers were sent round the districts and carefully instructed. Each man had his route and times marked out for him, so that all concerned knew what arrangements to make. In the larger stations private servants, boatmen, and others in special employ were attended to by travelling compounders who visited the different houses and so avoided the inconvenience of such men having to attend parades or hospital. This prophylactic issue lasted from June 16th to Dec. 1st. Altogether 496 501 doses (each of ten grains) were issued and about 650 pounds of quinine expended. Over the whole period of five months more than 80 per cent. of the population were receiving this drug, but the results were nothing like what they theoretically should have been nor were they consistent. Thus, for Ross the average admissions from July to December inclusive were as follows: two years no quinine, 150; admissions with quinine, 1902, 236. For

Aberdeen the average admissions from July to November inclusive were as follows: two years no quinine, 960; admissions with quinine, 1902, 922. (There were 300 increase in strength of this station.) For Haddo the average admissions from July to November were as follows: two years no quinine, 818; admissions with quinine, 1902, 877. (There was some increase in strength of this station.) For the Southern District the average admissions from July to November were as follows: three years no quinine, 1234; admissions with quinine, 1902, 1372. (There was considerable increase in the strength in the Southern District.) For Wimberley Ganj the average admissions from July to November were as follows: two years no quinine, 1671; admissions with quinine, 1902, 1759. (There was considerable increase in strength of this station, so that the fever admission rate per 1000 of strength is lower.) For the Female Jail the total admissions for fever in 15 months were as follows: (*a*) receiving quinine, 362, with an average stay in hospital of 5·5 days; and (*b*) not receiving quinine, 695, with an average stay in hospital of 7·35 days. (The strength of each class was nearly the same.)

At first sight it would appear that the issue of quinine has done little or no good or at most that the results have been inconclusive. But 1902 was a particularly unhealthy year and it may fairly be assumed that but for the quinine the malarial admissions would have been even higher than they were. Thus in the two unhealthy districts of Southern District and Wimberley Ganj the fever admissions in the pre-quinine period of 1902 were very much higher than in previous years, whilst after quinine was given the figures assimilate very closely. In the Southern District the three years' average malarial admissions from January to June inclusive were 1983, the average from July to November being 1234. The malarial admissions during the first period in 1902 with no quinine were 2938 (an increase of 955) and during the second period in 1902 with quinine 1374 (an increase of 140). In Wimberley Ganj the two years' average malarial admissions, from January to June inclusive, were 2149, the average from July to November being 1671. The malarial admissions during the first period in 1902 with no quinine were 2668 (an increase of 519) and during the second period in 1902 with quinine 1759 (an increase of 88). Thus quinine seems to have brought the very unhealthy year back to the level of the previous ones, although the population has increased. It is possible that the prevalent type of malarial parasite is largely responsible for the inefficacy of quinine as a prophylactic. One of the commonest parasites [illegible] and this, as [illegible] This fact, [illegible] nts existing without fever or symptoms, has an important bearing on malarial prophylaxis.

4. *The keeping of the population "fit" or in such a good state of general health that relapses or recrudescences are unlikely.*—This suggestion has been already discussed above under the relapse theory and little more requires to be said. It is obvious that the better general health our men are in the less likely they will be to succumb to malaria or other disease. But here the great difficulty is the interference with discipline and with the work of the administration. If labour in swamps, forests, and brickfields is prohibited, if work is to stop at every shower of rain, then I do not doubt that the sickness will decrease, but it does not appear advisable to recommend any such procedure or to attempt to interfere with necessary forms of convict labour in the settlement. Apart from any such steps we may improve the cooking and food-supply, we may introduce drying rooms, or issue extra clothes and so insure that the convict shall have dry things to sleep in. Sanitation, air space, and so on can be attended to and an occasional extra ration may be issued when the labour is excessively trying or hard. With this object in view it is proposed to utilise the Aberdeen drying room for one particular section of convicts during the wet season, to make such arrangements as will insure dry clothes to them and possibly to make special arrangements about their food. The results will be of great interest and will be carefully noted.

I have detailed above the four principal methods in which we may *combat malaria; it is now necessary* to discuss their relative merits and practicability.

It has been pointed out that as far as actual admissions go the mosquito net undoubtedly has the best effect, especially in the case of women living under jail conditions, not doing hard outdoor labour or exposed to rain and storm. But the ventilation difficulty is insuperable unless a very much larger amount of cubic space is provided—a larger amount than one could justly recommend. We are left, then, with mosquito brigades, prophylactic quinine, and general sanitation, and it is to these that we must look as means of checking malaria. I have endeavoured to show that the two former have already had some good effect. It is not unreasonable to hope that as experience is gained in the working of the mosquito brigades better results may be hoped for. *The prophylactic issue did do good and, I think,* not only by diminishing the admissions but over the whole settlement by lessening the periods of detention in hospital. This opinion is supported by the various medical officers in charge of the settlement hospitals, especially in the Female Jail. For general sanitation we must rely largely on the executive officers in immediate charge of the convicts. It is to their interest to have a low sick rate, for the fewer men they have in hospital the more easily can remunerative work be undertaken.

In conclusion, I advocate the following measures as the most suitable for checking malaria:—

1. The retention and, when necessary, expansion of the existing mosquito brigades. The expert trained part of each gang should be permanent and not available for other work. The coolies, drain-makers, &c., may, of course, be taken on and off as required, but the petty officer of the gang who knows what a mosquito larva is like and who can recognise culex eggs and knows the usual hiding and breeding places of the insects should be a fixture.

2. The general administration of quinine throughout the settlement in prophylactic doses.

3. *The establishment in the outlying and unhealthy stations* of branch dispensaries supplied with quinine and simple remedies. This plan was tried last year with much success both in the treatment of malaria and also of dysentery. It at times enabled us to get hold of patients earlier than we otherwise should have done and to save invaluable time in treatment. So far we are hampered by want of an adequate medical and dispensing staff, but it is hoped that more assistance will soon be available.

4. The provision of drying rooms or drying frames at every station and as a corollary the issue of extra clothing. I do not regard the drying room as a panacea for all evils, but I [illegible] clothes to sleep in and a good, [illegible] he comes home from work will enable him much more successfully to fight against malaria and other climatic diseases.

5. The restriction of such unhealthy forms of labour as firewood cutting, swamp work, &c., to the narrowest limits and the granting to men so employed of a small extra food ration. I regard the proposed substitution of coal for firewood [illegible] which cannot but have a go[illegible]

6. [illegible]l public interest in the healt[illegible] ike *to see competition* between stations as to which should have the lowest sick-rates and death-rates and whose malarial admissions should be fewest.

I should like to add a few remarks on the clinical characters of the malaria as locally observed and on the various methods of treatment in use.

Owing to the nomenclature adopted by the Royal College of Physicians of London we are obliged to define our malaria cases as "remittent fever" or "intermittent fever." This is a most unsatisfactory classification; many cases are remittent (in the sense that the temperature does not touch normal) for the first two or three days and then assume an intermittent type for a longer period. The patient in such a case may recover and be returned under either heading according to the ideas of the medical officer in charge of the case. On the other hand, the patient may die after a stay of some weeks in hospital, during the latter part of which stay the temperature may have been normal, intermittent, or even subnormal at times. Yet that case may reasonably be shown as remittent fever by one man and as intermittent fever by another. In the Fort Blair returns "remittent fever" may be taken to mean a severe type of malarial fever, and all cases dying from remittent fever are considered as malarial. These "remittent" cases occur in all parts of the settlement, but especially in the less cleared areas like the Wimberley Ganj and Viper subdivision. 148 cases with 48 deaths were thus returned in 1902. Many of the cases are rapidly fatal, the patients often being brought to hospital in a dying condition. Three or four days are a very common period for the patient to survive and delirium and coma are frequent before death. Hyperpyrexia is not common, though in one fatal case a temperature of 110° F. was noted and in another non-fatal case one of 107°. The men attacked are often old malarial subjects who have had many previous admissions for the disease; one patient had 24 previous admissions recorded, others had 15, 12, 10, and so on.

Malarial parasites are occasionally but not often found. As is well known in these pernicious cases parasites are often absent from the peripheral circulation. On post-mortem examination the outstanding features are the general congestion of the organs, especially of the brain and its membranes, the abundance of cerebro-spinal fluid, and the enlargement of the liver and spleen. The latter in 29 examinations averaged 22 ounces in weight, whilst the liver was frequently well over 70 ounces. These cases coincide very closely with those described by Pewintzky[4] of St. Petersburg in his essay on pernicious swamp fever. The possibility of some of these cases being cerebro-spinal fever was considered, but no definite evidence of this disease was obtained either clinically or microscopically.

Some of these remittent cases yield very well to treatment, but others are most intractable. Hypodermic injections of quinine are freely given, in some cases with much benefit, only rarely with none. Large doses of quinine by the mouth and by the rectum have also been tried. Methylene blue acts well in some obstinate cases. Latterly we have been giving "mass doses" of 30 grains of quinine by the mouth or hypodermically and in most cases with good effect. Often the temperature falls at once and remains down. In no case have we noticed ill-effects from these large doses, nor is hæmoglobinuria known.

An attempt is now made to examine microscopically the blood of every patient who comes to hospital complaining of fever and in this way the blood of 4304 patients has been searched. In many cases two, three, or even more examinations were made. Parasites were found in 2338 cases, the chief varieties noted being intracellular hyaline in 776 cases; hyaline ring form (malignant tertian) in 438 cases; pigmented intracellular in 704 cases; pigmented extracellular in 273 cases; crescents in 123 cases; segmenting forms in 20 cases; and flagella in two cases. More attention was paid to the presence or absence of parasites than to the particular variety, but it is interesting to note that quartan parasites were far from rare and would often resist quinine for some days.

It has been stated[5] that native children frequently harbour parasites without symptoms or rise of temperature. This I can partly confirm. Many children in whose blood we found parasites said that they were perfectly well, but on investigation they were found to be suffering from fever or from enlarged spleens. For example, *all* the children in the Female Jail and attending the Aberdeen school were examined. Of 158 children parasites were found in 58, and of these on examination 40 had fever or enlarged spleen, whilst 18 had no fever. The varieties of parasites were as follows: intracellular hyaline in 22 cases; intracellular pigmented in 23 cases; extracellular forms in 10 cases; and crescents in two cases. Again, at Haddo 68 healthy-looking persons (including Andamanese adults and children, and school children) were examined. Parasites were found in 11 cases, but all of these on examination were found to be suffering from slight fever.

With regard to the diagnosis of malaria by means of differential bloodcounts our results do not altogether agree with those of Rogers. Of over 63 counts and never of less than 500 leucocytes the average is: large mononuclears, 14 per cent.; lymphocytes, 25 per cent.; neutrophiles, 59 per cent.; eosinophiles, 5 per cent.; and others, 2 per cent. Rogers claims 15 per cent. of large mononuclears as a diagnostic sign in malaria, but we do not always get such a high percentage. We have taken specimens in which the crescents were double the large mononuclears and yet the percentage of the latter was only 14 per cent. For instance: large mononuclears, 14 per cent.; lymphocytes, 21·8 per cent.; neutrophiles, 60 per cent.; eosinophiles, 2·8 per cent.; and others, 1·4 per cent. The actual count was 501 and the crescents found numbered 137. The red blood corpuscles numbered 4,026,000 and the white blood corpuscles 6000 per cubic millimetre. On the other hand, in a case of dysentery where the patient did not complain of fever the following count was made: large mononuclears, 16·3 per cent.; polynuclears, 46·9 per cent.; lymphocytes, 34·2 per cent.; eosinophiles, 1·0 per cent.; and others, 1·6 per cent. The total count was 509 and the crescents present were 58. Here the malarial factor of large mononuclears was present, even though the usual dysenteric increase of lymphocytes was marked. Altogether, 265 differential blood counts have been made and many results of considerable clinical interest have been elucidated.

The convicts whom I have trained for microscopical work have been of the greatest use. These men are now well conversant with the different forms of parasites and they can make and stain their own preparations and in some cases can perform differential blood counts.

Port Blair, South Andamans.

[5] Report of the Malaria Commission of the Royal Society.

CHRONIC SUPPURATION IN THE MIDDLE EAR; THROMBOSIS OF THE LATERAL SINUS; GENERAL SEPTIC INFECTION; OPERATION; VENOUS TRANSFUSION; RECOVERY.[1]

BY W. M. WILLIS, F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE NOTTINGHAM GENERAL HOSPITAL AND TO THE NOTTINGHAM CHILDREN'S HOSPITAL.

CHRONIC suppuration in the middle ear is an extremely common disease and in view of the serious complications which sometimes ensue in consequence of its persistence it is well deserving of consideration and adequate treatment. However the inflammation originates, its persistence is to be found in the fact that inefficient drainage exists and this arises from several causes. There is an anatomical cause, which is a bar to efficient drainage in the case of suppuration within the tympanic cavity, inasmuch as that portion known as the attic is a sort of natural reservoir the floor of which is on a higher level than that of the floor of the general cavity of the tympanum and discharge from this position will only occur by overflow. It is common for the inflammatory process to involve the mastoid and here we have isolated cells which communicate with the general tympanic cavity through the largest of them known as the antrum. But the communication of the antrum with the tympanum is reduced in disease, so that efficient drainage is easily impaired. Thus from these causes we have a collection, varying slightly in amount from time to time, but always more or less existing, of what may be termed residual pus and this is present under a certain amount of pressure or tension.

In addition to the foregoing there is a pathological reason why efficient discharge is prevented and this is to be found in the presence of granulation tissue which is present in varying quantity both within the tympanum and on the outer side of the perforation in the tympanic membrane through which the pent-up matter originally made its escape and from which it has continued to issue. Two facts have so often presented themselves to me that I believe them to be true. The first is that the disease in question is eminently curable if freed rainage is established and maintained, and the second is that by reason of the long time some of these cases are allowed to persist either they must be looked upon with apathy or indifference or inadequately treated. If the bar to efficient drainage found in the granulations before alluded to be removed by treatment directed through the meatus and the aperture in the tympanic membrane be enlarged, and subsequently the tympanum be kept surgically clean, the patients in many of these cases will quickly get quite well. Some, however, will not and more extensive measures will be required. For these, when the less severe methods have been thoroughly tried and failed, the operation of opening the mastoid antrum or that known as complete mastoidectomy will need to be performed. This can be urged with much confidence as a cure can be promised and the mortality *per se* may be disregarded.

---

[1] A paper read before the Nottingham Medico-Chirurgical Society on Jan. 21st, 1903.

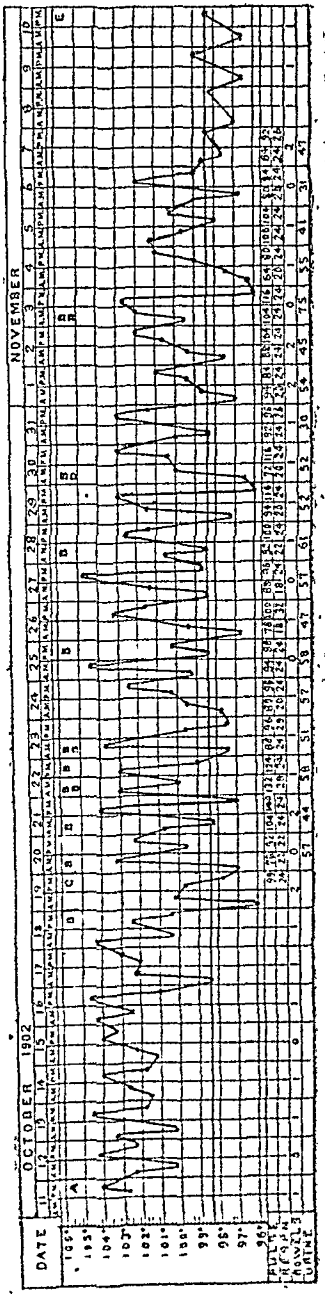
Cases will have to be decided upon on their own merits. In some an operation on the lines of that originally devised by Schwartze will be adequate but in others the more extensive proceedings practised and described by Stäcke will be needed. In either operation it is necessary to have an accurate knowledge of the anatomical structure of the parts and to exercise an abundant care in the steps of the operations; but provided these conditions can be complied with then the operations are reasonably safe and will afford good results. There will be careful and patient subsequent treatment necessary oftentimes, but in the end a cure will be effected.

These preliminary observations on chronic suppuration in the middle ear serve as a preface to the description of a case recently under my care, [illegible] was followed by thrombosis [illegible] into the jugular vein, and [illegible] infection as evidenced by si[illegible] and effusion of fluid into the pleural cavity and repeated rigors.

The patient, a male, aged 19 years, was admitted into the Nottingham General Hospital on Oct. 11th, 1902. He complained of pain in the head and gave the following history. There had been a discharge of matter from the right ear for nine years, it having followed an attack of scarlet fever. One week before admission he was seized with sudden illness and suffered from shiverings, vomiting, and intense pain in the head. Coincidently, he stated, the discharge from the ear ceased. His condition on admission was as follows. The temperature was 102 8° F He had pain in the head, especially on the right side, stiffness and tenderness of the muscles of the back of the neck, and some retraction of the head. There was an indistinct fulness to be felt in the neck high up just below the mastoid process. He was under the care of Mr. Joseph Thompson at this time who in view of the patient describing himself as feeling better, and as the temperature was falling, and there being no urgent symptoms, decided to watch the case for a time His condition remained much as above described until Oct 18th, when, for the first time since admission, he had a rigor which lasted for 20 minutes and the temperature rose to 105 2°.

On Oct. 19th Mr. Thompson, being unable to attend, asked me to see the patient and I then learnt the fact of the rigor on the evening of the 18th and found that during the time he had been in the hospital, whilst there had been no rigors other than that mentioned, yet there had been an extremely oscillating temperature which the accompanying chart will show. In addition to the temperature there were present headache, purulent discharge from the right ear, tenderness and stiffness of the muscles of the back of the neck, and a fulness down the upper half of the anterior border of the sterno-mastoid on the right side There was no optic neuritis.

I formed the opinion that he had a thrombosed lateral sinus and operated on the same morning I first turned down a semilunar flap about two inches in diameter, one side of the incision falling just behind the pinna and the other nearer the occipital protuberance. Baring the bone and drawing the pinna well forward I defined the bony margin of the external auditory meatus I then opened the mastoid antrum and cleared out a small quantity of inspissated pus which it contained. The next step consisted of trephining over the lateral sinus, exposing it by the removal of a half-inch disc of bone. An incision into the sinus revealed the fact that it was full of clot. Leaving the skull I now turned to the neck and exposed the internal jugular vein and found that the thrombus extended low down into this. I therefore ligatured it as low down as possible but could not get below the clot, and excised some one and a half inches of the vein above the ligature Returning to the skull I slit open the sinus and removed the clot and syringed through with sterilised water from the sinus to the jugular vein exposed in the neck, washing out thereby all the contained clot. Bleeding now became free both from the sinus and the jugular vein. The latter was therefore ligatured and the former was plugged with gauze, the hæmorrhage being thus easily controlled. The skull flap was then stitched into position, gauze plugs being in the sinus and in the mastoid antrum,



A, Admission. B, Rigor. C, Operation. D, Transfusion of three pints of saline solution. E, Got up; weight 9 stones 13 pounds. (On Nov. 28th the patient weighed 10 stones 1 pound.)

the ends of these issuing from the respective angles of the wound. The wound in the neck was then closed, and here I may say that this was a mistake, as it suppurated later and had to be completely undone; no harm, however, ensued.

By this complete operation I succeeded in removing nearly the whole of the septic clot and in addition cut off the main supply of septic material from entering the general circulation. I therefore looked for a cessation of the symptoms which had previously existed and hoped for an uninterrupted recovery. But in this I was disappointed. The operation was performed on Oct 19th and without giving the detailed notes taken from day to day suffice it to say that his symptoms continued. He had repeated rigors and high temperatures, a chart of which is appended. In the intervals of the rigors he felt fairly well but extremely weak.

On Oct. 25th my note says: "Breathing seems a little laboured; crepitations to be heard at the third left rib in front and impaired resonance at the left base." The physical signs remained thus for the next day or two and the rigors were repeated. I therefore resolved to adopt a method which I have not seen described as having been employed for the treatment of undoubted general septic infection.

I think there can be no doubt that it was a case of true septic infection as distinct from septic intoxication—i.e., septicæmia as against sapræmia—this view being supported by the fact that the main part, if not the entire supply, of septic material had been cut off, in spite of which the constitutional symptoms persisted and the condition in the lungs above described supervened. His only hope of recovery I considered lay in an increase in his power of eliminating the poison with which he was saturated and this I thought I could effect for him by largely diluting his blood. On Oct. 30th I therefore admitted into his right median basilic vein three pints of normal saline solution and one ounce of brandy. On Nov. 2nd my note says: "Has had no rigor for several days and there has certainly been an improvement in his condition ever since the transfusion." (See temperature chart.) "There are some dulness at the left base and a diminution of breath sounds and vocal resonance." On the 3rd I opened the median basilic vein of the left arm and removed nearly one pint of blood; I then transfused him with another three pints of normal saline solution and one ounce of brandy. On the 10th my note states: "He has improved immensely since the last transfusion. For the last three days his temperature has been practically normal." (See temperature chart.) On the 3rd the second transfusion took place and the temperature did not finally reach normal until the 7th, but in the intervening four days it was lower on the average and the elevations were not so great when they did occur. The chart for these days suggests a final flicker of the disease. The quantity of urine excreted subsequently to the transfusions did not show any great increase, though it was a little more, but there was marked sweating, his garments being frequently changed when wet through. It was in this way, possibly, that he eliminated toxic elements.

His final recovery was now uninterrupted and he is at the present time perfectly well and was shown at a meeting of the Nottingham Medico-Chirurgical Society on Jan. 21st, when this account of the case was read.

In conclusion, I would say that this short paper does not presume to be an elaborate account of the treatment of chronic suppuration in the middle ear, but merely expresses the opinion that that disease is eminently curable, and in view of its complications, should be cured. Secondly, in a brief and imperfect manner the lines on which such treatment should be carried out are suggested and outlined. Finally, in respect of the thrombosed lateral sinus, the operation described is in no way novel, but is the method very frequently adopted. In regard to the history of the case, however, subsequent to the operation, the evidence which the case affords seems to me to warrant the opinion that the patient's life was saved, when he would otherwise have died from septicæmia, by the transfusions which were performed and I venture to submit this for publication as I have not seen any similar case recorded.

Nottingham.

NEW WORKHOUSE INFIRMARY AT BIDEFORD.—The new workhouse infirmary at Bideford, Devon, was formally opened on June 2nd in the presence of a large gathering. The building will accommodate 38 persons and has been erected at a cost of £3248.

THE ANILINE DYES AS THERAPEUTIC AGENTS.

BY ANDREW BALFOUR, M.D., B.Sc., M.R.C.P. EDIN., D.P.H. CANTAB.,

DIRECTOR, WELLCOME RESEARCH LABORATORIES, GORDON MEMORIAL COLLEGE, KHARTOUM.

IN looking over the pages of that excellent compilation the *Medical Annual* for 1903 I was interested to find an article stating that methylene blue has been used with success as a sedative in cases of insanity. Ehrlich and Leppmann[1] in 1890 used this stain as an analgesic, administering it both internally and hypodermically, and reported favourably upon it. They were led to employ it from the fact that methylene blue will stain during life the axis cylinders of both sensory and motor nerve fibres. They stated that colouration of the nerves followed hypodermic injections. Combemale,[2] Gaillard, and Piotrowski denied this action, but, on the other hand, Pilliet[3] confirmed the observations of Ehrlich and Leppmann both as regards the staining of nerves and the analgesic effects, while Combemale admitted that the drug was useful in neuralgic and ataxic pains.

Some years ago I was engaged upon an investigation into the toxic properties of the dye stuffs which was embodied in an M.D. thesis,[4] but the results of which I did not publish. The work dealt chiefly with the effects of these dyes on the public health and more especially with the subject of river pollution, but to some extent it considered them from a pharmacological standpoint. I experimented largely with fish—roach, dace, and gudgeon—and was surprised at some of the curious results obtained. Of peculiar interest was the apparent affinity of certain of the aniline dyes for the central nervous system. Unfortunately neither the thesis nor any of my notes are at hand and I have to rely on my memory, but I well recall that both methylene blue, tetra-methyl-thionine-chloride, $C_{16}H_{18}N_3SCl$, and chrysoidine, the hydrochloride of diamido-azo-benzene, $C_6H_5N_2C_6H_3(NH_2)_2HCl$, exhibited this property to a marked extent. It was found that when fishes were placed even in very dilute solutions of these dyes (1 in 500,000 in the case of chrysoidine) they were speedily killed and on post-mortem examination were found to be stained through and through. The scales took on the stain vividly, the muscles were stained, but above all the brain and spinal cord were deeply coloured. It was hoped that this property might be utilised for staining *en masse* in histological work, but it was found on microscopical examination that the staining was diffuse and useless for purposes of differentiation. These two stains in particular seemed to pass very rapidly into the blood stream, no doubt *viâ* the gill arches, but chrysoidine was by far the most toxic. Indeed, it proved to be the most poisonous of any of the numerous aniline dyes employed. I am not aware that this dye has been used therapeutically though its disinfectant action has been tested.

Methylene blue has proved of value in malaria and to some extent also in bilharzial disease where it certainly produces sedative effects though its precise mode of action is unknown. It seems to me that chrysoidine might be given a trial.

I did not find it nearly so toxic for rabbits as for fish but it would have to be employed at first with caution and probably only after some experiments on mammals had been conducted. It has the property of precipitating the vibrios of cholera quantitatively from solutions in which they are held in suspension. The other azo compounds do not possess this property and I remember that in other ways chrysoidine was found to differ from allied chemical substances.

Any drug likely to benefit those suffering from the invasion of the *Schistosoma hæmatobium* (to adopt the most recent nomenclature) would prove a great boon in Egypt and it is just possible that chrysoidine might succeed where others have failed, while in the light of what I have stated it might also find a use in those nervous cases where methylene blue has been tried with gratifying results.

A CASE OF CONGENITAL DEFORMITY OF THE SKULL ASSOCIATED WITH OCULAR DEFECTS.

BY H. WORK DODD, F.R.C.S. ENG.,
OPHTHALMIC SURGEON TO, AND CLINICAL LECTURER ON OPHTHALMOLOGICAL MEDICINE AND SURGERY AT, THE ROYAL FREE HOSPITAL; SURGEON TO THE ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, ETC.;

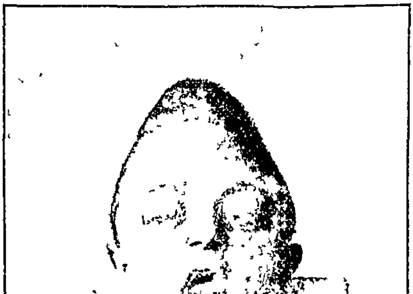
AND

W. HALLIBURTON McMULLEN, B.S. LOND., F.R.C.S. ENG.,
PATHOLOGIST AND CURATOR TO THE ROYAL WESTMINSTER OPHTHALMIC HOSPITAL; ASSISTANT OPHTHALMIC SURGEON TO THE MILLER HOSPITAL AND ROYAL KENT DISPENSARY.

THE following case is interesting both on account of the remarkable deformity of the skull and also on account of the association with this deformity of certain ocular defects

The patient is a boy, aged seven years, who was brought to the Royal Westminster Ophthalmic Hospital on account of the prominence of his eyes and slightly defective vision. He was born at full term after a somewhat difficult labour lasting 12 hours, but no instruments were used. His father stated that the head was deformed and the eyes were prominent at birth and that the shape of the head was then much the same as it is now. This statement is confirmed by Dr. Shelmerdine of Sandgate who saw the child shortly after birth. The patient is a backward child; he did not walk until nearly two years of age, became clean in his habits at two and a half years, and began to talk at three years. He has now been to school for two years but only knows a few letters and counts to four or five. For some time his parents have thought that his vision has been slightly defective They have also noticed slight deafness which has increased lately. He has never had convulsions or fits and there is no history of rash or other signs of inherited syphilis.

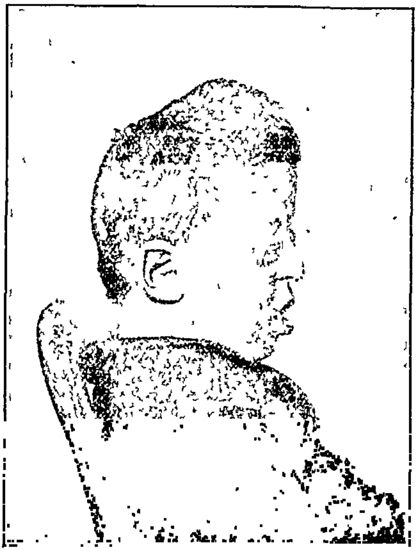
FIG. 1.



Aspect of patient, front view.

With regard to the family history the patient is the third child in a family of four. All the others are healthy, normally developed, and intelligent. There is no history of syphilis in the parents or of deformity, bone disease, insanity, or fits in any of his relatives.

FIG. 2.



Aspect of patient, side view.

The patient's present condition is as follows. (Vide Figs. 1 and 2.) He is of somewhat stunted growth (height three feet eight inches) but fairly well nourished. His head is of very peculiar shape, showing remarkable projection upwards of the anterior part of the cranium and very marked bulging in the temporal regions. The face is broad and flat; the eyes are very prominent and widely separated and there are traces of epicanthic folds; the nose is small, the bridge being short and narrow; the mouth is kept open, the lips are rather thick and projecting, and the tongue protrudes slightly between them. The neck is short, not unduly thick, and there is no enlargement of the thyroid gland. His gait is clumsy and slouching and he walks with a decided stoop, the head being thrust forward. His skin is thin and supple and his hair is normal. The principal measurements of the head are as follows: horizontal circumference, 48·5 centimetres; naso-occipital arc, 36 centimetres; binauricular arc, 34 centimetres; antero-posterior diameter, 15·6 centimetres; greatest transverse diameter (bi-temporal), 14 2 centimetres; binauricular diameter, 11·7 centimetres; distance between external angular processes, 10·2 centimetres; height of face, chin to hair, 14 5 centimetres; height of orbits, 3·3 *centimetres; and breadth of orbits*, 3·2 *centimetres*. The horizontal circumference is but little below normal, the average measurement according to Still being 49·5 centimetres at six years of age and 51·25 centimetres at eight years.[1]

The most remarkable features are the great excess in height and width The abnormal height is shown by the great relative length of the naso-occipital and binauricular arcs, the former being practically equal to three-quarters of the total horizontal circumference. The great relative width is shown by the high cephalic index—i e., $\frac{\text{breadth} \times 100}{\text{length}}$, which works out at 91·7; the average cephalic index in European skulls varying from 75 to 80 The excess in height is limited to the anterior part of the cranium, being due to a very marked upward projection over the frontal region extending back only as far as a point vertically above the external auditory meatus. The prominence so produced is somewhat compressed laterally and a low wide ridge can be felt in the middle line extending from the glabella to the back of the prominence. Just behind the prominence there is a small depression in the middle line, possibly indicating the site of the anterior fontanelle. The forehead is very high and vertical in the middle line, but on either side recedes markedly, forming a distinct depression above the outer part of the superciliary ridge. The excessive width is due to bulging in the temporal regions so great as to extend outwards on each side considerably beyond the level of the outer surface of the zygoma. This bulging is slightly greater on the left than on the right side, and on both sides it is limited above by the temporal ridge where a well-defined margin can be felt. The temporal muscle is palpable only for about half-an-inch above the zygoma. The superior curved line of the occipital bone is rather prominent and there is a slight mesial ridge on the interparietal portion of the bone and also along the line of the sagittal suture. There are no definite parietal eminences. The superior maxillæ are poorly developed; the palate is narrow and very highly arched and the premaxillæ are deficient; there are only one permanent incisor on the left side and no room for more on that side. Many of the teeth are carious.

---

[1] Goodhart and Still: Diseases of Children.

There are certain defects, probably developmental, in other parts of the body. On both sides, on extension and supination of the forearm, the head of the radius becomes subluxated forwards, apparently owing to laxity of ligaments. On flexion the head of the bone returns into place. This defect does not impair the usefulness of the limb or interfere with its movements. Congenital dislocation of the radius is a very rare condition; indeed, Stimson was of opinion that the majority even of the few cases reported as such were really cases of unreduced dislocation which had occurred in early life.[2] But in this case it appears probable that the slight defect is congenital as it is symmetrical and associated with developmental defects in other parts of the body. The phalanges of the great toes are abnormally broad: there is slight hallux varus, and the interphalangeal joints are ankylosed with some inversion. The arches of the feet are flat. The knee-joints are rather large and there is slight genu valgum.

With regard to the ocular symptoms, there is very marked proptosis, fully half of each eyeball being in front of the plane of the orbital margin. There is fine lateral nystagmus which is barely perceptible except on ophthalmoscopic examination; the ocular movements are otherwise normal. The pupils react to light and to accommodation. Ophthalmoscopic examination is difficult on account of the nystagmus. The optic discs are white, the margins are well defined, and the foramina of the lamina cribrosa are not visible. The veins are rather tortuous. The appearances suggest post-neuritic atrophy. Vision appears to be fair; the boy can count fingers at six metres with each eye. More exact determination is impossible on account of his defective intelligence. Hearing is slightly defective. He does not hear a watch ticking until it almost touches his ear. The external auditory meatuses and tympanic membranes are normal. The heart and lungs are normal.

The cranium in this case is rather of the oxycephalic or steeple-shaped type, the characteristics of which are great development of the vertical at the expense of the antero-posterior dimensions, the transverse measurements differing but little from the normal. Virchow found that cranial deformity of this type was due to premature synostosis of the parietal bone with the occipital and temporal bones, associated with compensatory development in the region of the anterior fontanelle.[3] The present case is remarkable on account of the very marked projection upwards of the part of the skull in front of the anterior fontanelle while the posterior part of the skull is no higher than usual, and also on account of the very great bulging in the temporal regions. Mr. Henry Power in 1894 published a case of remarkable cranial deformity associated with extreme proptosis.[4] The patient was an infant who died 30 days after birth. A cast of the head and a section of the head itself are now in the Museum of St. Bartholomew's Hospital. The similarity between the head of this infant and the head in our case is striking, the most noticeable features in both being great upward projection over the frontal region and bulging in the temporal region, but in Mr. Power's case these features are more marked than in ours. The skull of the latter case was examined by Professor D. J. Cunningham who found that every suture and synchondrosis of the skull was firmly ossified with the single exception of that between the basi-occipital and the ex-occipital.[5] Probably, then, the deformity in our case also is due to premature synostosis of certain cranial sutures with compensatory development in other regions. Thus it may possibly be explained as the result of early ossification of the lambdoid, parieto-temporal, all or part of the sagittal and perhaps of the coronal sutures, while the great upward development in the frontal region may be due to persistence of the frontal suture and overgrowth in that region.

Cases of cranial deformity associated with ocular defects form an interesting group. Such cases are rare but the ocular defects observed in them are so constant that it appears highly probable that these defects are dependent on, or at any rate are closely related to, the deformity of the skull. The variety of cranial deformity most commonly found in these cases is oxycephaly. Of a series of 19 published cases collected by Friedenwald, in 12 the crania were oxycephalic, in three scaphocephalic, and in the rest various other kinds of deformity were present.[6] Of the associated ocular defects optic neuritis or post-neuritic atrophy is the most important. As a rule, cases do not come under observation until they have reached the atrophic stage. The history of these cases is generally somewhat as follows. The cranial deformity is noticed at birth or very soon after. During infancy the children frequently suffer from convulsions and not uncommonly from epileptic fits when they grow older. More or less defect of vision becomes evident generally at an early age but sometimes not till later in life. Some of the patients are mentally deficient, but the majority possess average intelligence and a few are described as unusually bright and clever. When brought under observation the following are the ocular conditions noted. In nearly all cases there is proptosis, in many divergent strabismus. There is defect of vision varying from slight deficiency to complete blindness in one or both eyes. On ophthalmoscopic examination the discs generally present appearances characteristic of post-neuritic atrophy. Of Friedenwald's 19 cases atrophy was present in 15. In two cases optic neuritis of choked disc type was present when first seen, atrophy supervening later. In one case there was acute neuritis which was entirely recovered from, with restoration of sight. In a case published by Stood the fundus was normal although there was total blindness which was attributed to defective development of the occipital lobes.[7] In many cases vision gradually deteriorates, but in some it remains unaltered.

The pathology of these cases is somewhat obscure. The proptosis is due to malformation of the orbits, which, especially in oxycephalic skulls, are very shallow and abnormally high in proportion to their width, the vertical diameters being equal to, or greater than, the horizontal, as in our case, whereas in the normal skull the horizontal are greater than the vertical measurements. In Power's case the orbits were extremely shallow and very high, the roofs being nearly vertical in position. Weiss and Brugger, who carefully measured four oxycephalic skulls in the Heidelberg Anatomical Institute, found that the average depth of the orbits in these skulls was 10 millimetres less than normal and the cubic contents six centimetres less than the average. This abnormality in shape was principally due to the position of the great wing of the sphenoid which went to form the posterior instead of the outer wall of the orbit. Moreover, the roofs of the orbits were unusually highly arched. They consider that the shape of the orbits is such as to cause the eyeball to occupy an unusually high position and to this largely they attribute the proptosis.[8] Various opinions are held as to the cause of the optic neuritis. Post-mortem examinations have been made in only three of these cases. Michel found hyperostosis of the skull, narrowing of the optic foramina, and pachymeningeal thickening over the cortex.[9] Manz and Ponfix also

[illegible]

neuritis. This view, however, is not generally accepted because the optic foramina are usually of normal size in synostotic crania. Weiss and Brugger found no narrowing of the foramina in the four oxycephalic skulls which they examined, but in all four skulls they found the dorsum sellæ large and pushed forward and suggest that the neuritis may be due to pressure during early life on the optic chiasma or on the optic tracts in the neighbourhood. Virchow and Hirschberg attribute the neuritis to some inflammatory intracranial trouble, in most cases probably pachymeningitis which may also be the cause of the cranial deformity.[11] Virchow in his examinations of synostotic crania found that meningeal disease, especially pachymeningitis, was of frequent occurrence. Manz also favours the view that fœtal meningitis and osteitis are the underlying causes of the condition. Friedenwald suggests increased intracranial pressure, the result of premature synostosis, as the cause of the neuritis, which he therefore considers analogous to that associated with intracranial tumours. This explanation cannot be considered satisfactory until it is proved that optic neuritis occurring in cases of intracranial tumour is, in fact, due to pressure merely, a view not universally accepted. Moreover, in many of these cases there seems no reason to suppose that the cranial capacity is diminished and hence no increase of intracranial pressure would occur.

The cause of the whole condition remains quite obscure. In one of Hirschberg's cases there was a history of similar cranial deformity in a maternal grandfather; in another a definite history of syphilis in the parents; but in the majority of cases there is no history of deformity or specific disease in the parents and no evidence of the latter in the patients. The deformity is quite unlike that produced by rickets, and in rickets closure of the sutures is delayed; in these cases it is premature In our case there is no sign of rickets and there is no mention of its occurrence in any of the published cases. In the present case the existence of a slight degree of cretinism is suggested by the clumsy build, thick lips, largish tongue, and dull aspect. The shape of the head, however, is quite different from that usually associated with cretinism—viz., a broad short head, with flattened forehead, which Virchow found to be produced by premature ossification of the spheno-occipital synchondrosis. Moreover, the abnormal shape of the head was noticed at birth, but the cranial deformity of cretins develops gradually in the early years of life. His skin is thin, supple, and moist; there is no thickening of the subcutaneous tissue, prominence of abdomen, or lordosis; his hands and feet though rather large have not the thick podgy character of the cretin's; he shows considerable activity and curiosity, seldom remaining still for more than a few minutes at a time. It was considered advisable, however, to try the effect of a course of thyroid medication, but no benefit has resulted. It must be acknowledged that at present nothing is known of the ultimate cause of the condition; it remains a problem to be solved probably only when we possess a much fuller and more exact knowledge of ante-natal pathology.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—The annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held at the Royal College of Surgeons in Ireland on June 1st, Mr L H. Ormsby, President of the College, being in the chair Having approved of the report and statement of accounts, the meeting elected the committee and officers for the year.

BRITISH MEDICAL ASSOCIATION, DUBLIN DIVISION.—The first annual meeting of the Dublin division of the British Medical Association was held at the Royal College of Physicians of Ireland on June 4th, when the following office-bearers were elected for the ensuing year—Chairman, Mr. Arthur Chance; vice-chairman, Dr H T. Bewley; and honorary secretary, Mr. K. E L. G. Gunn. Dr. F. W. Kidd was chosen to represent the division of Dublin at the meeting of the British Medical Association to be held at Swansea in July next.

CHRONIC VOLVULUS OF THE SIGMOID FLEXURE; INTESTINAL OBSTRUCTION; OPERATION; RECOVERY.

BY HERBERT WILLIAM ALLINGHAM, F.R.C.S.ENG.,
ASSISTANT SURGEON AND LECTURER ON OPERATIVE SURGERY AT ST. GEORGE'S HOSPITAL;

AND

E. CHITTENDEN BRIDGES, M.D., B.S. DURH.,
CLINICAL ASSISTANT AT THE ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

THE patient was a man, aged 54 years, who for the previous 30 years had been subject to attacks of constipation recurring at periods of from four to six weeks and lasting from five to six days, accompanied by great pain in the lower half of the abdomen. Vomiting usually occurred towards the end of the attacks. At times there was considerable distension of the abdomen He had always been able to pass flatus per rectum during the attacks and there had been no difficulty with micturition. Towards the end of the attack the bowels usually acted very copiously as the result of medicine (blue pills, black draughts, or cascara sagrada). No blood, slime, or mucus was passed per rectum. There was no pyrexia or loss of weight.

The history of the present attack was as follows On the evening of April 18th the patient returned home from his office complaining of feeling cold. The bowels had acted once and but slightly. On the 19th, and again on the 20th and 21st, the patient took cascara sagrada with no result except that of much griping pain in the abdomen. There was no vomiting. On the 22nd, shortly after starting for his office, he had to return home on account of severe pain in the abdomen and he felt very faint. There was much straining at stool but with no result except the passage of flatus.

One of us (E. C. B.) saw the patient for the first time on April 23rd; he was lying on his back in bed with his legs drawn up and complained of considerable pain in the abdomen, especially over the left iliac region; this was much aggravated by digital pressure. He had been sick once that morning and had brought up the contents of his stomach. He had perspired very freely during the night and had passed flatus The abdomen was moderately distended and the percussion note was tympanitic. No peristaltic action of the intestines was seen through the abdominal wall which moved freely on respiration. The liver dulness was slightly diminished. On examination the rectum was found to be quite empty and ballooned; no growth was felt. The pulse was 68, regular, and of good volume The temperature was normal. The respiration was not hurried and was partly abdominal The tongue was covered with a dirty brown moist fur on the dorsum. The breath was foul but not fæcal The urine was loaded with urates. There was no albumin. An enema of soap and water with half an ounce of turpentine was ordered, but with no result except the passage of much flatus; an ounce of castor oil was therefore administered. On the 24th the castor oil had acted three or four times with much abdominal pain, a few drops of blood accompanying the motion. There was no slime The patient felt sick The temperature was normal. The pulse was 68; regular and soft. The tongue was furred. On examining the abdomen, which was much less distended than on the [illegible] swelling could be felt [illegible] patient much pain [illegible] more distinct and [illegible] As the patient appeared to be in considerable pain ten minims of nepenthe were ordered, to be repeated, if necessary, during the day. On the 25th the patient felt better; he had no pain to speak of and no nausea or vomiting He had passed wind freely after an enema (soap and water with half an ounce of turpentine) the evening before but no solid motion. There was no change in his condition on the 26th or 27th On the 28th he had a bad night. There was much abdominal pain and he felt very sick The breath was foul (? fæcal) The pulse was 80 and very thin; the temperature was 98·4° F. There were general uniform distension of the abdomen and much tenderness over the left iliac region and the sausage-shaped swelling could be distinctly felt. Mr. Allingham saw the patient in consultation and agreed that immediate operation should be performed.

Operation.—The ordinary incision for left inguinal colotomy was made but only collapsed small intestine presented itself. On enlarging the wound upwards and downwards and passing the fingers towards the middle line an enormously distended gut was felt which was with considerable difficulty brought into the wound; this was punctured and the gaseous contents were allowed to escape; the difficulty experienced in bringing the gut into the wound was found to be due to adhesions between the coils of the intestine. On drawing the gut out of the wound and examining it it was found to be a volvulus of the large intestine (sigmoid flexure which was at least 3 feet long), to which was attached a very long mesocolon and many adhesions which were evidently of long standing, as was borne out by the history of the patient. The adhesions were broken down and the volvulus was reduced. Before the wound was sewn up the sigmoid flexure was attached by two sutures to the abdominal wall, one at the upper part of the wound and one at the lower, the object being to prevent a recurrence of the volvulus. With the exception of slight thrombosis in the left leg the patient made an uninterrupted recovery.

Remarks by Mr. ALLINGHAM.—From the condition found at the operation—viz., old adhesions at the seat of the twist of the gut—I am disposed to think that the volvulus was always present and only gave rise to symptoms when the part contained within the volvulus became distended with flatus and so caused the attacks which the patient had complained of for so many years. In the last attack, however, the distension of the gut became so great that the muscular coat of the bowel became paralysed from over distension. Since the operation there has been no return of the old symptoms. So that one may conclude that the sutures which were put into the gut to secure it to the upper and lower part of the wound have prevented the enormously long sigmoid flexure from twisting on itself again and so re-forming the volvulus.

Note by Dr. BRIDGDES.—It is now over 12 months since the operation was performed and the patient has had no return of his old symptoms. The bowels act regularly without medicine and he expresses himself as never having felt so well before.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF SEVERE UTERINE HÆMORRHAGE TREATED BY IODIPIN.

By GEORGE E. KEITH, M.B., C.M. EDIN.,

LATE ASSISTANT TO PROFESSOR OF CLINICAL SURGERY, ROYAL INFIRMARY, EDINBURGH.

THE patient was a single woman, aged 49 years, who had been suffering from menorrhagia and metrorrhagia for some years. Up to the age of 43 years she was quite regular and the amount of loss was normal. About six years ago she noticed that the flow began to last longer and that she lost more than formerly. This gradually got worse until two years ago, when she sought advice from various medical men and hospitals.

I saw the patient first in consultation with my sister, Dr. Gertrude Keith, on Feb. 18th, 1903, the period having ceased the day before. The hæmorrhage had become so severe and constant that the patient had had to give up her occupation and, indeed, work of any kind, the slightest exertion not only increasing the hæmorrhage but bringing on faintness and intense breathlessness. These symptoms had been going on for some months. She was fit for nothing and if she even sat with her legs hanging down she became breathless. She stated that she had been treated at a London hospital for the last 14 months with ergot and other drugs and, though she had taken the medicines regularly, the symptoms had continuously increased.

The menstrual history for the last 12 months was as follows. She had been twice free from hæmorrhage for 14 days and once for 11 days, but beyond that the longest interval had been five days. Her general condition was certainly very bad, dyspepsia, constipation, swollen ankles, dilatation of the heart, and all the signs of extreme anæmia being present. On examination the cervix was found to be large and hard while the fundus was heavy and lying backwards. After washing the skin of the outside of the thigh with bichloride of mercury solution I injected one drachm of the 25 per cent. solution of iodipin into the cellular tissue. This dose was repeated every second day till March 3rd when the flow came on. This was an interval of 15 days. During the first day she noticed no difference in the amount of the loss, and as it was still excessive I gave the iodipin every day until March 6th, when the period stopped. It had thus lasted for four and a half days, the shortest and best she had had for a great many months, as, with the exception of the first day, there had been very little loss. The general condition had now much improved and she was able to do a little light work in her home. After the period was over the iodipin was again given every second day from the 7th to the 20th, when it was given every day as the patient felt that the period was coming on; however, it did not. The second period after commencing this treatment began on March 31st, an interval of 24 days; it lasted four days and was normal in amount. Since April there has been only one period; this also was normal and lasted four days. On examining the patient in the middle of May I found the uterus to be smaller and softer and the cervix normal.

This case shows the benefit of iodipin in certain forms of uterine hæmorrhage and, though it is perhaps unfair to praise it on the strength of one case, the paper of Dr. J. A. Shaw-Mackenzie in THE LANCET of April 4th, p. 958, also goes to show the value of this drug. Here was this patient reduced to utter helplessness by uterine hæmorrhage; every known drug in such cases had been tried for at least 14 months, and instead of getting better she was rapidly getting worse and she had become an invalid and a burden to others. There was nothing before her but a life of misery until the menopause came, probably three or four years hence, or an operation of more or less severity. Should the operation have been resorted to, owing to her enfeebled condition, a long convalescence was before her. Instead of this convalescence, within a week of commencing the hypodermic treatment by iodipin she was better and long before it was finished she was able to resume her employment and had become a useful member of society again. This is a point that is too often ignored and the weary weeks and months necessary for convalescence are forgotten when a patient is hurried into an operation. The result we ought to strive for is the cure of the patient with as little mutilation as possible and in a way that will put her on her feet soonest.

So far I have not tried iodipin in any case of definite fibroid tumour but my brother (Mr. Skene Keith) is getting good results in several cases.

Charles-street, W.

EMBOLISM IN ACUTE RHEUMATISM.

By A. BROWNLIE, M.B., CH.B.

ON March 16th I was called to see a boy, aged eight years, whom I found suffering from well-marked symptoms of acute rheumatism with endocarditis. This was his first attack. There was also considerable broncho-pneumonia of both lungs. At the apex and in the axilla a well-marked systolic murmur was heard. Pericarditis did not develop during the course of the illness. He had always enjoyed good health previously. On the 24th I found him in the following condition which, his mother informed me, came on quite suddenly during the night. There was complete right hemiplegia with aphasia, the right side of the face, arm, and leg being involved. The upper branches of the facial nerve were not affected as the orbicularis palpebrarum and frontalis muscles were intact, this fact clearly pointing to a supranuclear lesion. It was also noted that the voluntary movements of the face were more impaired than the emotional. Electrical tests were not applicable. The hypoglossal nerve was also involved, the patient being unable to put out the tongue straight, but it deviated toward the paralysed side. The arm was more completely paralysed than the leg. The thoracic and abdominal muscles were not involved. Hemianæsthesia was present and was more marked in the arm. The deep reflexes were increased in the arm and leg, ankle clonus being well marked.

With the exception of [illegible] bases of the lungs the patient's [illegible] iderably improved up to May 5th, [illegible] failure presented themselves, cyanosis being a prominent feature for two days before death which occurred on the 9th. The ultimate cause of death was evidently asthenia. There was no improvement in the hemiplegia and aphasia during the illness. No secondary contractions developed. Unfortunately, I was unable to obtain a necropsy.

Apparently, the case was one of embolism of the left middle cerebral artery with softening of the parts supplied by it, including the posterior part of the internal capsule. The case is interesting as, according to an eminent authority, embolism is rare in the acute endocarditis of rheumatism.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

ST. GEORGE'S HOSPITAL.

A CASE OF SIMULTANEOUS AMPUTATION OF BOTH LEGS; *RECOVERY.*

(Under the care of Mr. G. R. TURNER.)

FOR the notes of the case we are indebted to Mr. Lawrence Jones.

A man, aged 35 years, was picked up unconscious on the railway line on Feb. 3rd, 1902, and was admitted into St. George's Hospital under the care of Mr. G. R Turner. On admission the left leg was found to be completely severed from the trunk at the centre of the calf and the right leg to be hanging by the peronei tendons and divided at a rather lower level. The only other injury was a small scalp wound. He was very much collapsed and had evidently lost much blood; the pulse was almost imperceptible, beating 150 to the minute, and the surface of the body was cold and sweating profusely.

The patient was taken to the operating theatre without delay and after a rectal injection of saline solution and brandy and the administration of 10 minims of liquor strychninæ subcutaneously, gas and ether were given and both legs were amputated simultaneously, the left by Mr. Turner and the right by Mr. Jones. The condition of the man was so critical that very little time was lost in rendering the skin aseptic. On the right side Stephen Smith's method through the knee-joint was employed, but on the left there was not sufficient sound skin for the flaps and the femur was divided just above the condyles. Hæmorrhage after removal of the tourniquet was very slight, the popliteal artery on each side being the only vessel that required a ligature. Large drainage-tubes were used and the patient was sent back to bed in a very collapsed condition. During the night slight improvement was shown under the free use of brandy and strychnine and saline enemata.

Progress was maintained until Feb. 5th when the patient vomited several times and complained of feeling hot. The temperature rose to 103° F. and the right stump began to look red and inflamed. In a few days there was a free discharge of pus on this side and a slough, of about the size of a half-crown, formed; on the left side there was also a small slough. The temperature gradually fell and the discharge lessened, the former reaching the normal on the 14th. The sloughs separated on March 4th and both wounds were soundly healed on April 1st, when the man was sent to a [illegible] tely, it has been found impos[illegible] charge from the home and so [illegible]

Remarks by Mr. JONES.—Recovery after amputation through both legs is a sufficiently rare event to warrant the publication of the above case. The main points about the case are, firstly, that the patient was subjected to as short an operation as possible, the amputations being performed simultaneously with this idea; and, secondly, the free use of stimulants before and after the operation. A good many cases of recovery after multiple amputations have been reported singly in THE LANCET; similar cases to the above have been published by Hewetson[1] and Stirling.[2] Successful cases of amputation through both legs below the knee-joint have been reported by Tyson,[3] Rundle,[4] O'Callaghan,[5] and Crompton.[6] But in the statistics of amputations in general the death-rate is high; thus out of 400 cases of amputation given by Dent and Bull[7] seven were dou[illegible] all; and [illegible] extremit[illegible] results[8] and six out of 13 in those of the Newcastle Infirmary.[9]

SWANSEA HOSPITAL.

A CASE OF DOUBLE GANGRENE WITH DOUBLE AMPUTATION AT ONE YEAR AND NINE MONTHS.

(Under the care of Dr. R. C. ELSWORTH.)

FOR the notes of the case we are indebted to Dr. Alan H. Muir, house surgeon.

A female, aged one year and nine months, was admitted to the Swansea Hospital on Jan. 31st, 1903, as a case of gangrene exhibiting a line of demarcation. The child was very ill with a temperature of 102° F. The pulse-rate was 160, irregular, and hardly to be felt. The respirations were 48 and all the usual signs of septicæmia were present. The stench was appalling. The right foot hung on by the posterior tibial vessels and the left foot was in a similar condition. Higher up the legs the skin was broken in several places and there were a few bedsores. Under chloroform Dr. Elsworth amputated both limbs below the knee, obtaining flaps in the best way possible, whilst Dr. Muir [illegible] The [illegible] ampu[illegible] anæs[illegible] The [illegible] patient [illegible] hypo[illegible] [illegible] ectum [illegible] were given every three hours for the first 24 hours. The child showed evidence of the severe toxæmic condition for some time. The temperature for the first eight days ranged from normal to 103°. The wounds healed by first intention and the little patient was discharged in a healthy state and became an inmate of Mr. Barnardo's Home. The condition seemed to have commenced as an acute epiphysitis.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

A Statistical Inquiry into the Prognosis and Curability of Epilepsy based upon the Results of Treatment.

A MEETING of this society was held on June 9th, Mr. ALFRED WILLETT, the President, being in the chair.

Dr. W. ALDREN TURNER read a paper on the above subject which will be found at p. 1650 of our present issue.

In the discussion which followed Dr. FLETCHER BEACH drew attention to the confirmation afforded by statistics to the general view that cases in which there is no hereditary history are the most likely to improve. The rule that the in[illegible] of heredity was more obvious when both parents [illegible] were epileptic was not limited to epilepsy but was a rule common to most hereditary diseases. The large proportion of confirmed cases which had commenced in early childhood was an interesting fact which awaited explanation. In regard to the duration of treatment after the last fit, there seemed to be a lengthening of the period during which it was considered desirable to maintain treatment before the disease could be regarded as cured.

Dr. G. E. **Shuttleworth** laid stress on the importance of statistical inquiry and gave particulars of a series of 340 cases of epilepsy in board school children, of whom 17 per cent. were fit to continue with the ordinary courses of instruction, 27·5 per cent. were able to profit by the modified instruction provided at special schools, and 40 per cent. required special institutional treatment. He referred to the popular opinion that epilepsy was favourably influenced by marriage and quoted a case which was strongly opposed to this view.

Dr. W. H. **Blake** had obtained good results in the treatment of epilepsy with sulpho-carbolate of sodium and believed that in many cases the stomach was the seat of peripheral irritation. In cases arising at puberty he relied on treatment with salicylate of sodium.

Dr. G. **Newton Pitt** emphasised the two facts that the proportion of cures appeared to be no greater since the introduction of bromides than previously, and that cases in which treatment failed after having been carried out for one year were not likely to be arrested. He asked for some rule as to the administration of bromides in cases in which there had been a remission for two years or more.

Dr. H. **Batty Shaw** drew attention to the similarity of Dr. Turner's statistics to those given by Sir William Gowers in regard to the frequency of a history of heredity in cases of epilepsy.

Dr. D. A. **Shirres** referred to the value of Babinski's sign as an indication of organic disease.

Dr. **Turner**, in reply, stated that he regarded the convulsions as only one symptom of the disease. A more important element was the mental factor and it was on this that the prognosis depended more than on the convulsive factor. He was inclined to attribute the intractability of epilepsy in early childhood to the special mental conditions of that period No general rule could be given as to the administration of bromides after a period of remission, but each case must be treated on its own merits. He considered that the statistics of the older observers should be regarded with caution in the absence of strict definition as to what constituted cure.

ISLINGTON MEDICAL SOCIETY.

The Medical Problems of Alcoholism.

A discussion on the Medical Problems of Alcoholism took place at the last meeting of this society for the session 1902–03, on May 18th.

Professor G. **Sims Woodhead** having been asked to open the discussion from a physiological and pathological standpoint, said that he was almost afraid to come before them with a tale that he had been telling so constantly for some time past. As, however, the discussion was to be a very general one it might perhaps be as well to have a few statements and suggestions which might serve as direction posts to indicate a possible line of discussion. It must be remembered that he approached the question from the point of view of a total abstainer—a convinced "teetotaler" if they liked—and therefore that he held stronger views on the subject of alcoholism than did many of his friends. He observed that in Germany and Switzerland, where men were now making a scientific study of the alcohol question, the physiologists, alienists, and some of their hygienists were also becoming convinced abstainers. He pointed out many experiments on the action of fairly strong alcohol on the protoplasm of plants and lower animals. There could be little doubt that the functions of such protoplasm were seriously interfered with and that ultimately, if the action were continued, marked degenerative changes were inevitably produced. It had long been suspected and even recognised that alcohol probably acting as a protoplasmic poison was in some way or other responsible for the fibroid condition met with in cirrhosis of the liver and more recently the association of fatty changes in the liver with the exhibition of large and continuous doses of alcohol had come to be looked upon as a commonplace of pathology. He should, however, leave these conditions as associated with the liver and see if they could not satisfy themselves that alcohol as a poison had a far more wide-reaching effect. Alcohol as a poison appeared to act in two ways. First it acted upon the protoplasm of the different cells of the body, causing in many cases a rapid degeneration, the evidence of which was manifested by the presence of fat in the cells of various organs, by cloudy swelling, by the disappearance of Nissl's granules, or by the stunting and clubbing of the twiglets on the long processes of the nerve cells and the moniliform thickening of these processes. At the same time the poison acting on the connective-tissue cells in the immediate neighbourhood, all much less highly developed and therefore more readily stimulated to proliferation, caused an increase of these cells near the seat of degeneration. In very chronic cases these connective-tissue changes appeared to be primary, but he thought that although they were the changes that were most prominent and permanent, they were in most cases quite secondary to, and dependent to some extent upon, the more important degenerative changes first mentioned. This might, however, be a primary change especially when occurring in the walls of the blood-vessels or in tissues richly supplied with lymphatics. In connexion with changes in this latter position he pointed out that alcohol not only impaired function in one direction, it had a direct effect in bringing about a retention of the waste products of the body in the tissues themselves and in the fluids in which these tissues were bathed. These waste products being of a highly poisonous nature acted along with the alcohol in increasing the extent and severity of the degenerative and irritant processes of which mention had been made. Reference was made to the experiments carried out in connexion with the study of the effect of alcohol in preventing the acquisition of a state of immunity against disease-producing micro-organisms and their toxins. Professor Woodhead thought that they were only on the threshold of this subject as yet, but sufficient information had been acquired to justify the hope that still more would ere long be garnered. The popular notion that the effects of large doses of alcohol, especially when repeated, could be slept off in a night was absolutely erroneous, as was also an idea that it was a valuable food. Its action as a poison was far more important than its action as a food, and although a spurt had been made in bringing up evidence as to the food value of alcohol it was daily becoming more evident that its rôle was pathogenic rather than nutritive. In conclusion Professor Woodhead quoted the experiments of Kurz and Kraepelin[1] to show that the foundations of chronic alcoholism might be laid sooner than is generally supposed They say: "A single dose of 80 grammes of alcohol (2⅘ ounces) does not pass off quickly and perfectly but leaves behind an after-effect which lasts more than 24 hours. If this dose is repeated in 24 hours a gradual increase of effect is produced which we must designate as the commencement of chronic alcoholism and this is already very evident after 12 days' action by a depreciation of faculty to the extent of 25–40 per cent."

Dr. J. G. **Glover** said that of all questions affecting the health of nations and patients few were more important than that of the careful and intelligent use of alcohol. He did not pretend to give any demonstration of the truth of his opinions. They had only the value of impressions produced on a practitioner with an average open mind who had lived long enough to have seen the profession swayed with violent waves of opinion in favour of different methods of treatment and who remembered, in respect of this subject, great discussions and great variations of practice and who had made it more or less an anxious study. He had been much impressed with the views of medical men entitled to be leaders. Sir William Jenner once said to him—Sir William Jenner was not a teetotaler—"I have come to the conclusion that if a man has to work hard he must eat moderately and drink nothing." The view of his friend and mine, the late Dr. Edmund A. Parkes, reached after careful experiments, was that only an extremely small amount of alcohol could be dealt with or used by the system. The burden of the testimony of their leaders before the Lords' Committee—and it could not be gainsaid—was in favour of extreme moderation and they agreed in warning the public that quantities which the "man in the street" might consider moderate often led to inconvenient and pathological results. But the quantities consumed were enormous and showed no satisfactory signs of decrease, though large sections of the community took none and others little; so that there must be large portions of the community who were actually soaked and saturated with alcohol. There was a very general consensus of opinion in the profession that alcohol was not necessary for the young, that in their diet it was misplaced, and that even in acute depressing diseases they needed none or little. On this last point, what made a great impression upon him (Dr. Glover) was the teaching of Sir William (then Dr.) Gairdner in 1864 as to the treatment of typhus fever in Glasgow with little or no alcohol, showing that he treated 189 cases below 16 years of age, of which only one patient died, a child aged six years, who was admitted into the hospital in a moribund condition. Dr. Gairdner reckoned that if these 189 cases had been treated on Dr. R. B. Todd's system instead of one death—and that in a moribund child—there would have been from 30 to 35 deaths. These cases were treated without stimulants except in the rarest cases. Of 406 patients admitted above the age of 16 years 17 2 per cent. died. Dr. Todd's mortality from typhus fever in London with huge quantities of stimulants was, according to Dr. Murchison, 25 per cent. In recent days the value of alcohol in the treatment of cardiac failure, in fever, and in other states had been much discussed. Dr. H. D. Rolleston, in an address to the North London had spoken as follows: "At on a *the* remedy for failing heart ir lered that it should be given with no niggardly hand in bad cases, but gradually, partly from observation of cases and partly from experience of others, especially from consideration of facts insisted on by Dr. Graham Steell—that cardiac dilatation is frequently in the otherwise healthy due to alcoholic excess—I have come to distrust the value of alcohol in large I hat disease the myocardium ic action of one poison and to suffer from the effects to rely on other means and chiefly on the hypodermic injection of strychnine." Dr. Glover had a strong conviction that as life advanced in those who had been in the habit of taking stimulants moderately the quantity should be decreased rather than increased. The prolongation of life depended much on the glands and the blood-vessels and alcohol was not good for the liver and the kidneys. It tended to destroy fine special cells, whether of the liver, the kidneys, or the brain, and to replace them by fibrous tissue; it senilised, it favoured degeneration, and impaired both the liver and kidneys, so that the system could not dispose of alcohol as it could when those glands were younger. The principle "*vinum lac senum*" was a most doubtful one, even when the wine took the form of whisky, according to the prevailing fashion. Here Dr. Glover wished to record his belief that the notion that whisky was a benign and innocent form of alcohol which young and old, healthy and gouty, might indulge in with impunity was one of the greatest delusions of this generation, and nothing was more striking than the hold that this delusion had of the more educated classes. He was told by one of his most intelligent patients, himself a commercial traveller of high character and great and long experience, that "commercial travellers drink more whisky than they ever did; they take it in the morning and at all times; and they all say that their doctors told them they might. Men used to take sherry with lunch and dinner and port after; now they take whisky instead." On the need for diminishing the amount of alcohol taken quote the opinion of so the late Sir William of this natural tendency—i.e., to diminish the proportion of stimulants taken as age creeps on and the nutritive processes decline in elasticity and power—are neglected or resisted by the unwary; they imagine that the quantity of stimulants which they tolerated with impunity, or even took with advantage, during the vigour of manhood cannot hurt them in later life. This, I believe, is an error, the commission of which tends to accelerate senile decay and to provoke fatally tending organic changes in the kidneys, liver, and arterial system." As a curious illustration of the defective intelligence of educated people in this matter he was often struck with the levity with which they might see gentlemen, even young gentlemen, enter a railway bar and toss off a glass of whisky, sometimes very little diluted and sometimes, he feared, raw. Even in Scotland, with all its centuries of education and its high religiousness, there was still little or no decline in the consumption of whisky; and there was some years back, if there was not still, a club known as the "Ten-tumbler Club," the members of which included some distinguished Scots. He had seen the *Times* recently quoted as to criminal statistics in Scotland: "Remarkable is the increase of crimes against property without violence, of malicious injury to property, and of drunkenness and disorder." The special committee on mental cases of the parish of Glasgow lately reported as follows: "The committee views with concern the fact that, of 565 admissions to the two asylums as insane and 213 to the poorhouse as cases of incipient insanity during the 12 months, no fewer than 259 or 33 per cent. have become chargeable to the parish through alcoholic indulgence. ...... In the large majority of cases the conditions and surroundings were good, and the earnings in 19 typical cases were from 19*s*. to 60*s*. per week. It is beyond question, further, that a large number of the insane sent to the asylums in previous years, and still inmates thereof, are cases of the same nature." Late reports of Dr. T. S. Clouston, of the Royal Asylum, Edinburgh, equally show the increasing influence of alcohol in the causation of insanity. Recent revelations as to physical defects and degeneration in the large English town populations as revealed by the tests applied to recruits were very painful reading. In the Manchester district only 1200 out of 11,000 men offering themselves for enlistment during the recent war were found up to the standard of what a soldier ought to be. In a report of Colonel Bennett, the inspector-general of recruiting, it was said that 75,750 men were medically examined last year. As many as 22,286, or, 29 04 per cent., were rejected for various ailments or want of physical development. Dr. Glover associated this physical with the excessive use of alcohol. It rful cause of deterioration, but s he could make out, to about working-man, affected gravely his own nourishment and that enditure were reduced even by many quarts of milk weekly or an extra room to live in. Too much was made of mere legislation for the treatment of habitual drunkards. This was beginning at the wrong end. They must begin with sounder views of diet for children, for young people, for patients, for servants, and for families generally. In America this was a subject of teaching in the schools, and so it should be everywhere with us if more intelligence was to be brought to reduce the amount of alcohol consumed by the nation, which so retarded social and physical improvement. There were some diseases in which alcohol, according to popular views, was beneficial—e g., consumption. In a very interesting article Dr. W. H. Dickinson[2] showed conclusively from the clinical and pathological records of St. George's Hospital that the free use of alcohol by persons in the liquor trade did not prevent phthisis, as even so acute an observer as Dr. Walshe thought, but promoted it. As an instance of the old ideas in the treatment of carbuncle it was a common practice to push the administration of stimulants, especially port wine. He (Dr. Glover) hat such treatment was a vas common in oldish people, and whose organs and blood-vessels were older than their years, sometimes having sugar or albumin in the urine. They were easily overpowered with stimulants and were made worse. Such cases were far better treated with rational diet and local antiseptic dressings with or without incisions. The treatment of fevers by Sir William Gairdner he had already referred to. Perhaps the malpractice and folly of the indiscriminate prescribing of stimulants could be best understood by considering for a few seconds the careless use of the word "weakness" by the public and too often sanctioned by the profession. Debility or weakness might mean *anything*; it meant actually nothing. But it was the foundation upon which much of the abuse of stimulants actually rested. The facile diagnosis of "only weakness" usually covered ignorance or carelessness. A patient came to them complaining of feeling weak. He had, perhaps, been taking on his own account what he called "strengthening" things—"nourishing stout," port wine, or rump steaks. All the time he had probably some considerable disorder—catarrh, some error of metabolism, or some block of digestion or assimilation. His tongue might be furred or his urine loaded with lithates or slightly albuminous, or he might have touches of rheumatism or gout. The correction of these states was the obvious treatment and all the so-called tonics in the Pharmacopœia with the soundest whisky and the most nourishing stout were so many delusions to which the intelligent practitioner should be no party. That was the real tonic treatment which aimed at the correction of latent or obvious errors in the working of the system or of its individual organs. Alcohol might easily aggravate such evils. Dr. Glover then spoke of beer alcoholism in Germany and in England and of intemperance of women. In Islington in the last ten years there had died from cirrhosis of the liver 286 men and 300 women. Dr. Glover ended by saying that he was not a teetotaler and that he did not think that teetotalism was a practical doctrine for a northern nation. Certainly alcohol could not be dispensed with as a remedy, or by some persons as a part of diet. All the same, he regarded the present consumption of it as simply disastrous and discreditable to the public intelligence. All the great European nations were showing a wise anxiety on this subject. On the whole, he had a low opinion of alcohol in any but the lightest form and quantity and thought that there could be no doubt that recent research and careful clinical observation pointed to the wisdom of greatly reducing its consumption with food, never using it casually or carelessly and prescribing it with more precision and with a high sense of medical responsibility. The profession of France, Germany, and Russia were exercised much on this problem and that of Great Britain would not be behindhand.

---

[2] Occasional Papers, 1[illegible] to 1[illegible].

Dr. ALEXANDER MORISON was glad that Professor Woodhead did not exclude a therapeutic use for alcohol from consideration. The effect of alcohol on the higher cells of the body was shared by other agencies of admitted therapeutic value as strychnia, opium, and belladonna. The therapeutic use of drugs was frequently and admittedly an intoxication with them, or, to use the language of the clinician, it was generally necessary to induce in some degree the physiological action of a drug before we could hope to influence the organism beneficially. Did the argument apply to alcohol in health or in disease? They did not use drugs in health or endeavour to induce in some degree their physiological action when a person was well. But drugs were not food, which alcohol in some measure was. Still they could not beneficially live on alcohol and it might be stated generally that a healthy man needed no alcohol even when fatigued, for the fatigue of a healthy man would soon pass off with rest, ordinary food, and natural sleep. A man who led a strenuous life and was free from organic disease might, however, be fatigued to that extent at which we had apostolic authority for believing that a little wine might be good for the stomach's sake, for in such circumstances it might aid digestion and relieve vascular tension. The danger of this was that moderation was not widespread. There was risk of excess fostered in many ways by social customs and by commercial interests. Unfortunately the wise counsels of the physician were not likely to be taken seriously by alcoholic Philistines. It was not as a stimulant to the digestive process that alcohol found its most serious application in medicine. It was as seriously combating threatened cardiac failure that alcohol found its most useful applications in medicine, in serious and sudden emergencies, in the prolonged strain of exhausting diseases, and in the shock, either of mental distress or of severe pain either in the heart itself or in some other region reacting on the heart. In such circumstances half an ounce of brandy, undiluted or little diluted, was most useful, acting directly upon the nervous regulative apparatus of the heart. Dr. Morison showed by slides the rich endowment of the heart with peripheral nerves. He thought that they should beware, lest for political, economic, or philanthropic reasons they held their hand in the practical field of rational therapeutics.

Dr. J. L. HEWER remarked that it was interesting to hear that the early nerve changes as demonstrated by the microscope could be absolutely recovered from, but he would like to know the definite point at which recovery was impossible. They must all know the patient who took nearly a bottle of whisky a day with apparent impunity. A great deal must depend upon individual idiosyncrasy.

Dr. J. FORD ANDERSON said that he would like to know if the moderate drinkers—those who like himself had been in the habit of taking a glass of wine with their meals—would suffer the degeneration of cells which Professor Woodhead had mentioned. He understood that most of the observations on alcoholic poisoning in man had been made in pronounced cases of the alcoholic habit, and if this were true it would be misleading. Dr. Anderson further remarked on the almost universal use of alcohol by nations and on the general distribution of alcohol in the vegetable kingdom and thought that people could not avoid partaking of alcohol sooner or later if they used as a diet the fruits of the earth. He cited a case in illustration where fermenting grapes caught fire when a lighted match was applied. He regarded alcohol in carefully regulated doses as a food and as a producer of force in the malnutrition and malassimilation of chronic disease and in the exhaustion of acute diseases. When alcohol was administered in such cases it not only produced direct stimulation but it underwent combustion and the tissues of the patient were spared, and he cited as an example cases of pronounced anæmia where iron and feeding seemed to fail until port wine or an equivalent was ordered. Alcohol also in health generated energy when to use the French proverb, "Il n'y a que le premier pas qui coûte"; when the work was really beyond their strength but yet must be done a glass of wine often overcame the initial difficulty of starting and the vital powers would carry them through. This did not seem, however, to be true when the muscles were tired, muscular fatigue being more relieved by tea than by alcohol. Dr. Anderson also expressed disapproval of the prevailing laxity in ordering spirits without specifying the quantity, especially to young people who were likely to end by taking more than the physiological dose.

Mr. T. D. JAGO said that he was a teetotaler but he was quite alive to the value of alcohol, especially in obstetric and other emergencies.

Professor WOODHEAD by way of reply to Dr. Morison's point that alcohol in injuring the protoplasm only did what strychnia, opium, and other drugs, confessedly useful medicines, did, agreed, but he pointed out that whereas they were prescribed only as drugs in precise quantities and for a limited time alcohol was used loosely and after the occasion for prescribing it had passed.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

Adjourned Discussion on (1) the Care and Treatment of Persons of Unsound Mind in Private Houses and Nursing Homes, and (2) Lunacy and the Law.

A MEETING of this association was held on May 15th under the presidency of Dr. JOSEPH WIGLESWORTH.

Dr. HENRY RAYNER resumed the adjourned discussion of two papers read at the meeting held at Derby County Asylum on Feb. 12th—namely: (1) the Care and Treatment of Persons of Unsound Mind in Private Houses and Nursing Homes, by Dr. Ernest W. White;[1] and (2) Lunacy and the Law, by Dr. T. Outterson Wood.[2] Dr. Rayner said that the first point was the desirability of having early care of mental cases, and the second point was that such care should be efficient. The legalisation of the treatment of early mental cases might be regarded as fairly settled and it was to be hoped that the Lord Chancellor would succeed with his Bill at the third attempt. Dr. Rayner, however, feared that the privilege might be abused unless some limitation were placed upon its use, though the basis of such limitation was matter for discussion. The persons most suitable to take care of early cases were those who had had considerable asylum experience; the next best persons were old asylum officers; and after them ladies who originally had experience in nursing their own friends and then had taken to nursing work. On the other hand, general nurses were too stereotyped in their habits to be successful with mental cases. Persons without experience should never be allowed to have the care of those difficult cases. He had seen mental cases treated with care and kindness but yet to their detriment;

sometimes, again, they were allowed to be wet and dirty and to masturbate to any extent With regard to the limitations referred to, it was possible that the Commissioners in Lunacy might be inclined to grant licences to persons who would take charge of early mental cases, but his own feeling was that that association, which had done so much in the matter of training attendants at asylums, might set to work, by examination, and perhaps by teaching, to furnish the public with a trustworthy body of people to have charge of incipient cases of insanity

Dr L A. Weatherley (Bath) said that the first 14 years of his professional life were devoted largely to the care of the insane in private dwellings, and in 1880 he read a paper, which was discussed at two meetings of the association, on the same question He published the paper as a book and dedicated it to the late Earl of Shaftesbury In that book he proposed to make the system of single treatment of the insane a definite legalised system—i e, to eliminate those who, simply for payment, took patients into their houses when they had no special knowledge of mental disease. He advocated the issuing of licences to persons who should have such care, not by quarter sessional districts, but by petty sessional districts, as the latter would know more of the people in their particular area In a letter written to him the late Earl of Shaftesbury said that he did not object to the principle of placing the insane in private care, but were any relative of his afflicted with insanity he would place him or her in a house along with many others in preference to any retreat for a single patient Almost all reformers in lunacy matters were so carried away by the claims of the patient that they totally forgot the claims of the public who had a right to security from danger and annoyance Sir William R. Gowers [3] in his paper read before the association, seemed to want to make it possible for people to be placed under the care of almost anyone so that what was called the stigma of insanity should not rest upon the patient and his family, but Sir William Gowers probably forgot that the majority of those even who were sent to private houses were not sent with their free will, but against it A great deal depended on the kind of person with whom the patients were to be placed He (the speaker) thought that the voluntary boarder system ought also to be very widely extended and that each asylum should have a separate department and dietary for private patients

Mr J F Briscoe recommended the passing of a motion stating that the association disapproved of the system now practised with regard to single care and private nursing homes, and suggesting to the authorities some stringent methods with regard to the better regulation of single care cases nursing homes, and other places for persons of unsound mind

Dr David Bower reminded the members that the association had done all that it could to get the Scotch provision inserted into the new Bill But, on the other hand it was very necessary not to make the treatment of lunacy absolutely a matter of free trade, and it was desirable to have such precautions as those laid down in the two papers under debate

Dr G Savage said that a large proportion of friends would not have their relatives certified, and until by some sort of police action, they could be forced against their will something must be done in the way of recognising single homes He agreed that there should be a kind of notification of patients and of homes As an illustration of the qualifications of some of the persons who wished to have patients in their houses he mentioned that a parson s wife had written to say that unless he could send a patient who could pay £1000 a year and would cause no trouble her husband would have to give up his carriage as he had met with heavy financial losses In some of the cases in which application had been made to him by medical men to have cases for private care the men were well qualified but the houses were unfit for various reasons such as being semi-detached and having no garden In another case the relatives said that a medical man was no good—they would have a nurse and run the risk They did so and the patient committed suicide

Dr H F H Newington (Ticehurst) said that Dr White s paper might be regarded as an answer to that of Sir William Gowers who seemed to want to tear down the provisions of the lunacy law too much and to allow of the treatment of excessive numbers of patients in private houses In some cases, of course, good results were more likely to follow by placing patients in good hands under private care than in public institutions but Sir William Gowers went much further than that

Dr Douglas (London), Dr F W Edridge Green (Hendon) Dr A J Alliott, Dr Henry Forbes Winslow, and Dr W Lloyd Andriezen also took part in the discussion, after which Dr White and Dr Wood replied to the points raised by the various speakers

EDINBURGH MEDICO CHIRURGICAL SOCIETY

Ichthyosis —Roentgen Rays in the Diagnosis of Lung Disease —The Nauheim Bath —Sialogogues

A meeting of this society was held on June 3rd, Dr C E. Underhill, Vice President, being in the chair

Dr D Chalmers Watson showed a case of Ichthyosis in a girl who had benefited considerably by treatment In December she presented an entire absence of hair over the body, while that on the head was scanty At the present time hair was growing on its normal situations on the arms and on other parts and that of the head was luxuriant. Dr Watson also exhibited microscope slides showing the Histological Appearances of the Skin of a Seventh month Fœtus—a sister of the above mentioned case of ichthyosis He also exhibited a case of Rheumatoid Arthritis with several interesting features, as pigmentation, tremors cachexia, and tender deep seated areas in the muscles, chiefly of the neck

Dr D Lawson (Nordrach on Dee) read a paper on Roentgen Rays in the Diagnosis of Lung Disease and illustrated it with a large number of lantern slides The paper will shortly appear in full in The Lancet —In the discussion which followed Dr Alexander James Dr F Gardiner, Dr W Allan Jamieson, Dr G Lovell Gulland, Dr D C A McAllum, and Dr Norman Walker took part

Dr A. D Webster contributed a paper on the Saline Effervescing Bath (Nauheim Bath) and Resisted Exercises in the Treatment of some Heart Cases He said that the special treatment was indicated (1) in enfeebled states of the heart such as might be due to physical strain to psychical stress or worry, and to toxins, and (2) in some cases of valvular disease He discussed the effects of the special bath as regards the temperature of the water, the dissolved salts, and the carbonic acid gas, comparing them with the cardiac remedies—arsenic, strychnine the nitrites, and digitalis He said that the temperature of the bath in its action on the heart corresponded to digitalis The salts in their action on the heart and skin corresponded to arsenic and in their action on the vessels corresponded to the nitrites The carbonic acid gas by its stimulation of the sensory nerves corresponded to strychnine The bath acted as a powerful stimulant both thermic and mechanical with special influence on the vagi The general effects of a course of these baths were a sense of well being good sleep, improved appetite, increased warmth of the skin and increase of the body weight

Dr W G Aitchison Robertson read a paper on Sialogogues and their Therapeutic Employment. It was well known that certain substances and especially those which were pungent to the taste when chewed, caused a rapid flow of a watery fluid into the mouth Portions of each of the substances investigated were masticated for a period of 30 minutes, the amount of saliva being collected and measured every two minutes In this way it was noted whether the flow was constant and uniform or whether it varied in its amount, alkalinity, or starch-converting power The alkalinity of the saliva was estimated in each case by means of very sensitive litmus paper The starch converting power was estimated by allowing a measured quantity of the saliva secreted under the stimulation of each agent to act upon a measured quantity of starch mucilage for a definite period At the end of this interval the amount of sugar produced and the degree of dextrinisation of the starch which remained were determined It was found that rhubarb, mustard, pimenta cinnamon, and marsh mallow called forth but a relatively small increase in the salivary flow, whilst such agents as calumba, orange peel, gentian, cinchona, and cusparia induced a much more copious secretion. Heading the list were pyrethrum, colchicum, ginger, horse radish, and black pepper. The alkalinity of the saliva was found to vary within such small limits that for practical purposes it might be said to have been uniform. As regarded the starch-converting power of the saliva it was found that catechu, rhubarb, alum, and borax entirely inhibited the action of the salivary ferment. On the other hand, most of the drugs which induced a copious flow of saliva exerted what might be termed a normal sialocinetic action—that was, that the saliva secreted under their stimulation acted in a normal way on starch mucilage. For practical purposes it might be considered that the useful sialocinetic agents were confined to the vegetable kingdom. Many individuals found difficulty in the digestion of starchy food and such cases could often be benefited by slow mastication and proper insalivation of the amylaceous constituents of the meals. Dyspeptics were also advised after meals to chew for ten minutes or so one or other of the more potent and palatable sialogogues. In hyperchlorhydria the onset of pain was usually delayed until some time after partaking of a meal. It was, therefore, desirable to secure the digestion of the amylaceous constituents of the meal before the free acidity checked proteolysis. This could be done by increasing the flow of normal saliva, which, also, by its alkalinity delayed the presence of free acid. In many cases of feeble gastric digestion the fault was due merely to a diminished activity in the gastric juice, both hydrochloric acid and pepsin being present in less than their normal amounts. When saliva was introduced into such a stomach it had the effect of stimulating a more copious as well as a stronger secretion. Thus an increase in the saliva which was introduced caused a larger amount of gastric fluid to be secreted. In many such cases Dr. Robertson had found that great benefit was produced by a stimulation of the salivary secretion by means of palatable vegetable sialogogues, such as ginger, gentian, peppercorns, or cusparia. In certain cases other means of treatment must first be employed, as, for example, multiple fermentations in the stomach must be treated by lavage and the exhibition of antiseptic agents, such as salol, salicylate of bismuth, or naphthol.—Dr. Underhill, Dr. H. M. Church, Dr. G. Keppie Paterson, Dr. Webster, and Dr. W. Craig took part in the discussion.

---

[3] The Lancet Nov 2nd, 1902, p 1309.

Clinical Society of Manchester.—A meeting of this society was held on May 20th, Dr. T. A. Helme, the President, being in the chair.—Mr. J. E. Platt made a communication upon Bronchocele, especially from the point of view of treatment. He briefly reviewed the various forms of chronic bronchocele and referred to a few points in their etiology, pathology, and symptomatology. In cases of parenchymatous bronchocele he had found considerable benefit from the administration of iodine and potassium iodide internally, but these and all other internal remedies were practically useless in adenomatous cases. In the latter the only effective treatment was operation with enucleation of the tumour. The general parenchymatous enlargement of the gland which often accompanied adenoma usually subsided after the removal of the adenoma. In simple parenchymatous cases which resisted medicinal treatment operative measures should consist in partial excision of the gland or scooping out of its interior. Mr. Platt also referred to the symptoms of absorption of thyroid secretion which sometimes occurred after operation and showed a number of charts illustrating special observations upon this point.—Dr. Arnold W. W. Lea read a paper on Acute Recurrent Hydronephrosis and related the notes of four cases treated by operation. The condition was characterised by recurrent attacks of acute abdominal pain with severe constitutional disturbance and associated with rapid swelling of the kidney and temporary hydronephrosis. It may be found along with mobile kidney, but extreme mobility of the kidney often existed without any evidence of hydronephrosis. Mr. W. Bruce Clarke in 1893 described this condition as "acute renal dislocation" and considered that the kidney slipped downwards beyond the costal margin. In the cases described by Dr. Lea the reduction of the kidney even under anæsthesia was impossible owing to the great increase in the size of the organ. The cause of this condition was temporary ureteral obstruction. Slight degrees of ureteral obstruction were common in mobile kidney, producing some hydronephrosis, but in the acute cases an additional element was introduced —viz., sudden kinking or torsion of the ureter. Valvular folds were frequently present in the upper part of the ureter near the renal pelvis. Sometimes also strictures occurred from adhesions, traction by bands, or more rarely by a calculus. Reference was made to an interesting paper by Barg of Paris,[1] who had examined the ureter and renal pelvis of a large number of newly born infants. The pelvis of the kidney showed great variation in size and shape, and the angle of insertion of the ureter might be vertical or almost horizontal. The form most liable to lead to hydronephrosis was a voluminous renal pelvis with the ureter entering at an acute angle. In these cases, which were rare, slight degrees of movement of the kidney, such as might be produced by sudden strain or effort, led to obstruction of the ureter and acute hydronephrosis. Other factors, such as congenital stenosis, valves, and twists, also conduced to it. The production of recurrent hydronephrosis was largely dependent on the congenital disposition of the ureter and renal pelvis. In these cases slight descent of the kidney, not recognisable clinically, might lead to acute ureteral obstruction. The symptoms might be very severe. In one case the attacks came on at frequent intervals without obvious cause and were accompanied by intestinal obstruction due to displacement of, or traction on, the colon. A distinct tendency existed for the attack to come on just before a menstrual period. This occurred in two cases and might suggest a pelvic cause for the symptoms. The attacks might last three or five days and then within a few hours the kidney returned to its normal size and all the symptoms disappeared. In the intervals the patients might be well but they were usually neurasthenic and had constant aching in the loin. The diagnosis was simple if a definite tumour could be felt, but in the earlier stages of ureteral obstruction with dilatation of the pelvis the symptoms might be very severe in the absence of any definite tumour. The treatment must be mainly surgical. The kidney must be exposed, and in the great majority of cases nephrorrhaphy effected a permanent cure. In slight cases it was unnecessary to drain the pelvis. If, however, the kidney was hydronephrotic the pelvis must be incised and a careful examination made of the upper end of the ureter. If no obstruction was found the pelvis might be sutured and the kidney fixed. Nephrorrhaphy was carried out by Dr. Lea in all the cases. In three the pelvis of the kidney was opened and in one case it was thought advisable to drain for a few days. In each instance a permanent cure was obtained. It was important not to delay operation too long, as otherwise the kidney might be irretrievably damaged. There was also a great tendency to the development of pyonephrosis in these cases, due to an ascending infection from the bladder or possibly secondary to adhesions forming between the colon and the perirenal tissues.

Dermatological Society of Great Britain and Ireland.—The annual meeting and conference of this society took place on May 27th. The following gentlemen were elected as officers for the ensuing session:—President: Dr. J. H. Stowers. President-elect: Dr. H. Waldo. Vice-Presidents: Dr. P. S. Abraham, Dr. R. L. Bowles, Dr. James Galloway, Dr. A. J. Harrison, Dr. J. F. Payne, Dr. H. H. Phillips-Conn, and Dr. P. H. Pye-Smith. Treasurer: Dr. C. H. Thompson. Honorary secretaries: Mr. A. Shillitoe and Dr. W. B. Warde. Council: Dr. Wallace Beatty, Dr. H. A. G. Brooke, Sir Alfred Cooper, Dr. H. Radcliffe Crocker, Dr. A. Eddowes, Mr. Willmott H. Evans, Mr. W. T. Freeman, Dr. A. J. Hall, Dr. E. G. Graham Little, Mr. George Pernet, Mr. George W. Sequeira, and Dr. Edward Stainer.—Dr. William Thomas Corlett, professor of dermatology and syphilology, Western Reserve University, Cleveland, gave an address on the Present Epidemic of Small-pox throughout the United States, together with a short consideration of the different types of the disease, their recognition, and some of the influences of vaccination, illustrated by lantern slides. By way of introduction he called attention to the similarity in the methods employed in combating the disease both here and in America. To the great Sydenham they were indebted for placing at rest, he trusted for all time, the uncertainty which existed concerning the identity of certain affections—e.g., chicken-pox, measles, &c.—which presented, it must be acknowledged, certain fundamental characteristics which entitled them to be placed in a group by themselves—"the acute infectious exanthemata." He next spoke of the freedom from small-pox which the aborigines of the American continent enjoyed previously to its discovery by Columbus. The disease was carried to the island of San Domingo in one of the subsequent voyages, thence it spread to the mainland carrying consternation and death to the natives who, scattering far and wide, spread the new disease far into the interior. Small-pox was not unknown to the early settlers of New England and a few years after Jenner's great discovery in 1798 vaccination was practised in the infant republic of the New World. Attention was next called to the variability in severity of the different epidemics that from time to time had swept over the country, as well as to the various clinical types of the disease, the importance of which, the speaker thought, could not be too strongly emphasised. The epidemic of 1898 appeared, within a few months, in various States remote from each other. Thus in Boston and New York the disease assumed a virulent form and was from the first attended by a high mortality, while in Philadelphia, only about 100 miles away, it was so mild that the health authorities experienced difficulty in maintaining strict quarantine measures. In Ohio so mild was it that a correct diagnosis was not at first made, the disease being regarded as a severe form of varicella. Into Boston and New York small-pox was thought to have been introduced from Europe, and into Ohio from Cuba, where it was endemic, *viâ* the Southern States. A series of photographs, illustrating the various types of the disease, &c., was thrown on to the screen. Two factors, Dr. Corlett thought, should be taken into account in controlling or modifying small-pox: (1) vaccination; and (2) the as yet unknown condition of the variola virus itself. By vaccination small-pox might be stamped out of any community, as had been done in Germany. But it must be impressed on the laity that revaccination at least every ten years, or oftener during epidemics, alone insured complete immunity. As to the second factor, all they knew was that the epidemics varied greatly in severity, independently of the influence of vaccination. In the Cleveland epidemic the death-rate increased from about one-half of 1 per cent. for the first year to nearly 20 per cent. in the third and fourth years. The virus was supposed to have developed more virulent properties by successive transplantations. In conclusion Dr. Corlett spoke of the exclusion of the actinic rays of the solar spectrum in the course of treatment. The exclusion of daylight must be complete from the beginning of the eruption. To insure this Finsen recommended the suspension of a sensitised photographic plate in the room. The exclusion of the actinic rays in no way influenced the variola virus itself.—Dr. Harrison moved, and Dr. Radcliffe Crocker seconded, a very cordial vote of thanks to Dr. Corlett for the most interesting address which he had given to the society.

---

[1] Revue de Chirurgie, February, 1902.

GLASGOW SOUTHERN MEDICAL SOCIETY.—A meeting of this society was held recently under the presidency of Dr. D. Macgilvray. Dr. Bruce gave a most interesting account of his experiences in South Africa during the war which was much appreciated. At the conclusion he was cordially thanked for his lecture.—Dr. G. H. Edington then showed:—1. An Appendix which had been removed from a Right Femoral Hernial Sac. The appendix was tightly grasped at the orifice of the crural canal and protruded one inch into the sac. The sac was distended with fluid and was of about the size of a Tangerine orange and contained no other viscus. The appendix was pulled down, ligatured, and cut away. The stump was touched with pure carbolic acid and returned into the abdomen. The canal was closed by one suture passing through Poupart's ligament and the pectineal fascia The patient was a woman, multiparous, aged 50 years, and had no signs of strangulation, but she had complained of swelling in the groin, pain, and uneasiness. The swelling was irreducible and had no impulse on coughing. The duration of the illness was four days. She made an uninterrupted recovery. 2. A Sequestrum containing Temporary Molars and one Biscuspid Crown from the left upper jaw of a boy, aged six years, who had a severe attack of typhoid fever ten months previously. The necrosis followed sloughing of the cheek in the sixth week of the illness, but the sequestrum was not removed until eight months later. While in hospital a similar sequestrum had come away from the right upper jaw. The symmetry and the part of the jaw affected were in agreement with Salter's description of exanthematous jaw necrosis occurring after scarlet fever, measles, and small-pox. Dr. Edington having shown other specimens of a surgically interesting kind was cordially thanked for his demonstrations.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held on May 27th, Mr. W. B. Holderness, the President, being in the chair.—Cases and specimens were shown by Dr. G. L. Eastes, Mr. J. W. Gooch, Mr. W. H. Beresford, Dr. G. E Hale, Dr. F. E. Wood, and Dr. C. R. Elgood.—Dr. Harry Campbell made a communication on Respiratory Exercises and Thoracic Mechanics. He pointed out that the position of the chest most favourable to the pulmonary circulation was that of full inspiration, first, because in it the lungs were most stretched and their suction action on the heart was at its maximum; and secondly, because the "bed" of the pulmonary circuit being widest in the inspiratory position the resistance in the pulmonary circuit was at its minimum. Hence, in all cases of dyspnœa the thorax was maintained in the inspiratory position, physiological breathlessness, cardiac dyspnœa, spasmodic asthma, pneumonia, pleural effusion, and pneumothorax being instances in point. This truth did not seem to have been recognised by clinicians. Dr. Campbell said that much the most satisfactory way of developing the lungs was by the induction of physiological breathlessness, as by running, jumping, skipping, and the like, and not by gymnastic exercises calculated to over-develop the muscular system and to render the thorax muscle-bound. He further contended that writers on emphysema had failed to furnish a satisfactory explanation of the enlargement of the chest in this disease. The enlargement in question was to be explained first, by the necessity for a widening of the pulmonary vascular "bed" owing to the destruction of the pulmonary capillaries; and secondly, to the need for a tightening or tuning up (so to speak) of the relaxed pulmonary tissue so as to maintain as far as possible the pulmonary suction in the heart at its normal level.

Reviews and Notices of Books.

Obstetrics: a Text-book for the Use of Students and Practitioners. By J. WHITRIDGE WILLIAMS, Professor of Obstetrics, Johns Hopkins University; Obstetrician-in-chief to the Johns Hopkins Hospital. With 8 Coloured Plates and 630 Illustrations in the text. London and New York: D. Appleton and Co. 1903. Royal 8vo, pp. 845.

THE appearance of a work on obstetrics from the pen of Professor Whitridge Williams is a matter for congratulation. The amount of research which he has carried out upon many subjects in this field of medicine and the high character of all the work emanating from the Johns Hopkins University render the book one of special interest. The manual, although a volume of some 845 pages, is easy to read not only because the author has a pleasing style but also because he has arranged his material in a number of relatively short and concise chapters. To each of these a bibliography is appended containing a list of the most important original articles upon the subject treated of and there is a refreshing absence not only of old and obsolete theories but also of the old and obsolete drawings which even at the present time are so often handed on from one text-book to another. The book is profusely and well illustrated with eight coloured plates and 630 illustrations, almost all original.

In considering racial differences in the pelvis the author points out the interesting fact that contracted pelves occur several times as frequently amongst black as they do amongst white women (21 per cent. to 7 per cent.), while the frequency of operative deliveries is greater amongst the latter. This would appear to be due to the small size of the children's heads amongst the negroes. The description of the changes that occur in the decidua and the imbedding of the early ovum is particularly good. Professor Whitridge Williams is inclined to agree with Graf Spee's view that the origin of the amnion in the early human ovum is by an inversion of the wall of the original blastodermic vesicle, a view which has been confirmed by Selenka's observations upon monkeys and which is admirably illustrated by Spee's drawings of his earliest human ovum with an embryonic area 0·4 millimetre long. The account of the development of the early placenta is the best that has so far appeared in any text-book in the English language.

The author's views upon the antiseptic precautions necessary to be taken in the conduct of labour are very thorough. He advocates the permanganate of potassium and oxalic acid method of disinfecting the hands, and recommends that, before applying forceps, the genitalia should be shaved. We are afraid that women in this country are hardly educated up to this point of surgical cleanliness. We, however, entirely agree with the advisability of all such precautions being taken, but the difficulties of carrying out such an elaborate preparation in private practice are made a little too light of.

In the chapter upon the forceps it is recommended that it should always be applied to the sides of the child's head, the position of the lowest ear being first defined, and in the management of unreduced occipito-posterior presentations the application of the forceps to the sides of the head and the rotation forwards of the occiput after it has reached the pelvic floor are advocated. The forceps is then removed and re-applied. It is interesting to note that the author does not commend the operation of symphysiotomy. He does not agree with the claim that is made that it is a suitable operation for the general practitioner to carry out, and sums up his remarks upon the subject by writing "that he does not expect to perform symphysiotomy under any circumstances and believes that the present enthusiasm for it will eventually disappear." This view of the matter is one that has found a good deal of favour in this country and at the present day there is hardly a single English obstetrician of note who is an enthusiastic supporter of this operation. On the other hand, the induction of premature labour, a method of treating cases of contracted pelvis which is constantly being practised amongst us, finds but little support in this work. It must be remembered that the fœtal mortality is undoubtedly high, varying as it does from 12 to 45 per cent. and when we read that Professor Whitridge Williams has had a fœtal mortality of only 13 per cent. in a series of 278 cases of contracted pelvis in which premature labour was not induced the position which he takes up is in part explained. Bar, who has had a large experience of the induction of premature labour, has practically abandoned it and recommends the performance of Cæsarean section at term if spontaneous delivery does not occur. With this view the author is in agreement and he would limit the induction of premature labour to cases where the pelvis is normal but the child is abnormally large. If we turn to the account of the treatment of cases of contracted pelvis, a section in which the illustrations are especially good, we find that in flattened pelves with a conjugate diameter varying from 8 9 to 7·5 centimetres the performance of Cæsarean section or symphysiotomy is recommended if, after some hours of efficient second-stage pains, there is no likelihood of engagement of the head and the patient is in a good condition and in a well-regulated hospital. If, on the other hand, the patient is not placed under such favourable conditions and spontaneous delivery does not occur forceps should be applied obliquely to the head and a few tractions should be made. If the head shows no tendency to advance craniotomy must be performed. The method of treatment advocated is all in favour of a decided advance in the number of cases subjected to Cæsarean section so long as the patient is under favourable conditions, a plan of treatment which Professor Whitridge Williams thinks is likely to lessen very markedly the fœtal mortality while the maternal mortality will be reduced to a minimum.

The chapter upon Puerperal Fever contains an excellent summary of the bacteriology of the disease and in discussing the treatment the employment of the curette is unhesitatingly condemned. The administration of anti-streptococcic serum is not held to be of much value in the treatment of these cases, nor does the author think that the practice of removing the uterus with the idea of limiting the further spread of the poison is an operation likely to be at all commonly practised or of much avail.

The work can be recommended not only because it is well up-to-date, but because many of the methods of treatment advocated, although not in common practice at the present time, are likely to be the current teaching of the future.

Handbook of Climatology. By Dr. JULIUS HANN. Part I., General Climatology. Translated with the author's permission from the Second German Edition, with additional References and Notes, by R. DE COURCY WARD, Assistant Professor of Climatology in Harvard University. New York: The Macmillan Co. (London: Macmillan and Co). 1903. Demy 8vo, pp. xiv. + 437. Price 12*s.* 6*d.* net.

PROFESSOR HANN'S well-known "Handbuch der Klimatologie" first appeared in 1883. The present volume is an excellent translation from the second edition of 1897 of the portion dealing with general climatology. It forms a complete work in itself. Numerous references have been added and some changes have been made in the text with a view to bringing the subject up to date, but the translator points out that every change has been made with the full approval of Professor Hann. The translator likewise states that though some new examples of climatic phenomena have been added, chiefly from the United States, most of the examples given necessarily still relate to Europe, because the climatology of that continent has been studied more critically than that of any other region. Professor Hann's work certainly deserves to be better known in England and America than it is at present and the translator is to be congratulated on the English edition now offered to the public.

It would be impossible to discuss much of the work in a short review. The sections on winds are of great interest to medical men. Though all agree that a certain amount of movement of the air has a beneficial effect in maintaining the purity of the supply, yet most are convinced that strong, cold, and damp winds may be injurious to weakly and diseased persons. They exert a generally depressing effect and favour any tendency to bronchitis, and it is thus that Dr. W. Gordon explains the harmful influence of the west and south-west winds in Devonshire in regard to pulmonary tuberculosis. Moreover, cold strong winds induce persons to keep doors and windows shut and to remain in stuffy rooms. One of the great advantages of a sheltered sunny winter climate is that more time is likely to be spent in the open air.

Professor Hann selects striking and often familiar phenomena to illustrate elementary principles. Thus, he very clearly explains the causes of the usual morning and evening winds in mountain valleys and the apparent exceptions to the rule, such as in the Upper Engadine. The morning wind blows down instead of up the valley of the Upper Inn during the warmer months, whilst in the side-valleys the morning winds blow upwards according to the rule. Billwiller and others have shown that this apparent exception is due to the fact that the Upper Engadine is not inclosed at its upper end and that on the further side of the Maloja Pass, which is but little higher than the valley floor itself, is the head of the deep and well-warmed valley of the Maira (Upper Bergell) the air of which rises above the level of the Maloja Pass and descends the Upper Engadine valley. Professor Hann likewise explains the origin of the "Foehn" and other local winds for which various theories have at different times been propounded. The results of the studies of Erk, Billwiller, and Pernter show "that in the rear of the larger barometric depressions which usually pass by on the western or north-western side of the Alps there are developed local depressions with their own inflowing spiral wind systems along the northern border of the Alps and in the Alpine valleys themselves and that these are the immediate cause of the Foehn." This explains the local violence of the Foehn winds and their frequent occurrence in the eastern Alps, especially at Innsbruck, in apparent disregard of the general distribution of barometric pressure. Winds analogous to the "Foehn" of Switzerland occur in other countries and can be similarly explained.

In regard to the theory of Dubois concerning the great changes of climate to which the world has, according to geological evidence, been subjected the following conclusion is arrived at: "*One thing, however, is certain and this is* that in explaining the climates of the geological past the sun cannot be considered to be an absolutely constant source of heat. Hence, such considerations as those which have been urged by Dubois are perfectly legitimate."

In the portion of the book dealing with mountain climate the physiological effects of diminished atmospheric pressure and the question of "mountain sickness" are considered The effects of high altitudes on the blood are, of course, alluded to, but many observations on the subject remain unnoticed. Thus, though mention is made of the writings of P. Bert, Egli-Sinclair, A. L. Rotch, F. Viault, A. Muntz, and P. Regnard, those of F. Miescher, F. Egger, A. Gottstein, E. Meissen, G. Schroeder, von Pacht, S. E. Solly, W. A. Campbell, and H. W. Hoagland and other recent observers have been omitted. Yet it must be allowed that the whole subject of blood changes at high altitudes has even yet not been settled, and possibly a prolonged discussion of the question might be considered out of place in a handbook of general climatology.

We consider that the present volume should be in the hands of every student of general climatology since it is a careful, ably written, and trustworthy text-book on the subject.

LIBRARY TABLE.

The Castration of Cryptorchid Horses and the Ovariotomy of Troublesome Mares. By F. T. G. HOBDAY, F R C V S. London and Edinburgh: W. and A. K. Johnston. 1903 Pp. 105. Price 5*s*.—The treatment of cryptorchidism in the horse is not uncommonly a matter of necessity, as such an animal may at any time display a vicious and treacherous disposition. Mr. Hobday has collected in this little book an interesting series of consecutive cases of castration of cryptorchid horses and of ovariotomy of troublesome mares With regard to the fertility of such horses it is interesting to note that spermatozoa were demonstrated by Professor M'Fadyean not only in five of the cases where the testis was in the inguinal canal but also in two instances where it was in the abdominal cavity. Two of the colts were out of the same mare but by different sires, while three were by the same sire out of different mares. In regard to the troublesome mares it is not uncommon to get a condition of almost continuous œstrum which renders them too objectionable or treacherous to be used and the only thing to be done is either to sell the animal or to have it operated upon. The result of ovariotomy, as a rule, is good, except in the case of aged mares or in those in which the habit of kicking has been of long standing. The operation is performed through the vagina and the fact that in two cases the animals were ridden within seven and ten days respectively shows how little shock is produced The book is an interesting proof of the success with which major surgical operations can be performed upon equine patients under anæsthetics and with modern antiseptic precautions.

JOURNALS AND MAGAZINES.

The Medical Magazine.—The issue for May contains some remarks upon the Midwives Act by Dr. W. J. Sinclair which are prefaced with the hope that future amendments to the Act will be in the direction of greater stringency and efficiency. He considers that more definite limitations should be placed upon the action of the midwife of the future and that her scope should be clearly outlined in a manner which is not likely to obtain under the Act as it stands. Dr. Frederick Taylor contributes an article which supports his well known views upon the treatment of chlorosis, and the editorial notes touch briefly upon general events of current interest in the medical world.

New Inventions.

AN INHALER FOR THE ADMINISTRATION OF SOMNOFORM.

THE accompanying illustration represents an apparatus which I have now used for some months for the administration of somnoform, consisting of a celluloid face-piece connected by means of a right-angled metal tube to a rubber bag. The face-piece is lined with lint which is maintained in position by a special spring, horseshoe in shape, preventing collapse of the lining during any deep inhalation by the patient. The lint can be thus readily changed and a clean piece substituted. In using this apparatus the dose of somnoform required for a single administration, producing an anæsthesia averaging from 90 to 120 seconds, is about two and a half cubic *centimetres—i.e., half the dose* of the drug marked on the bottles in which it is supplied for use with the handkerchief cone adopted by Dr. Rolland. The apparatus was made for me by, and can be obtained from, Messrs. Down Bros , Limited, 21, St. Thomas's-street, London, S E.

ENEMA SYRINGE.

MR. R. J. REUTER of 6, Well-street, Jewin-street, London, E.C., has brought to our notice a new enema syringe presenting certain novel features in its parts which are of distinct hygienic advantage. To begin with, there are no metal parts at all in the appliance, and therefore no metallic contamination can take place or deterioration or break-down of the valves due to rusting or corrosion. The valves, which permit of the passage of the fluid by the action of the elastic chamber in one direction, are also made of vulcanite. The cannula terminates in a circular slit so that the fluid is delivered in the shape of a spherical film. There is thus a considerable but gentle distribution. The vaginal injection tube may be replaced by a vulcanite rectum pipe. The valves can easily be removed for cleansing purposes and all parts can readily be washed with an antiseptic solution. Altogether the special construction of this enema syringe is calculated to insure the use of a perfectly clean instrument for the particular purpose for which it is designed.

THE LANCET.

LONDON: SATURDAY, JUNE 13, 1903.

The Metropolitan Hospital Sunday Fund.

NEXT Sunday, June 14th, is Hospital Sunday. All our readers know it, and the strenuous exertions of the supporters of the Fund and of ourselves to bring the occasion prominently before the public have led to the fact being common knowledge also. What remains for us to do on the eve of the great annual collection is very little. We can only add to our advocacy of the movement a few last words in reinforcement of the extraordinary efforts being made this year to ensure a record result. The actual and final advancement of the claims of the Hospital Sunday Fund upon the public does not rest with us. The maintenance, efficacy, and well-being of the institutions which exist for the healing of the sick and maimed poor of all creeds and nationalities in this great metropolis will be pleaded for to-morrow by the ministers of all sections of religious opinion in churches and places of worship dedicated to various creeds. Our part has been to supply the pleaders with facts in aid of their arguments and with concrete reasons upon which to base their demands for liberal alms. Our annual supplement strives to do these services, and we are proud to know that its publication in our columns and its dissemination in places of worship a week prior to the collection are regarded by the managers of the Fund, as well as by the occupants of the most important metropolitan pulpits, as a powerful adjuvant to the cause.

Thirty years ago the idea of instituting an annual collection in the metropolitan places of worship for the metropolitan hospitals and dispensaries first took shape, and the leading part that was played in the movement by the proprietors of this journal, and especially by our then editor, the late Dr. JAMES WAKLEY, by Sir SYDNEY WATERLOW, and by the late Canon MILLER of Birmingham may properly be recalled. At that time it was difficult to arouse public interest in the needs of the hospitals. The value of the work done for the sick and injured poor of London by many noble healing institutions was not recognised by the public to the same extent that it is now, and the powerful patronage under which the Metropolitan Hospital Sunday Fund and King Edward's Hospital Fund for London flourish to-day had not yet been extended to them. It is known now to all England that the KING OF ENGLAND makes the condition of, and the treatment of, helpless sufferers in his imperial capital the subject of his peculiar and anxious care. When he instituted the Fund that bears his name we stated definitely that it was in no sense to be regarded as a rival or a supplanter of the older charity, a point which has since been emphasised on several occasions. This year HIS MAJESTY has done more. With a magnificent spirit of coöperation in the work of the Metropolitan Hospital Sunday Fund he attended St. Paul's Cathedral last week, accompanied by the QUEEN and many members of the Royal Family, and there took part in an enthusiastic service at which a special appeal was made on behalf of the London hospitals. A magnificent sermon, clear, brief, eloquent, and pointed, was preached by the Bishop of STEPNEY, and no less a sum than £4300 was received at the collection made upon the close of the service on behalf of the Metropolitan Hospital Sunday Fund. The impetus and publicity that HIS MAJESTY'S action has given to the work and claims of this Fund will certainly have enormous influence upon the donations of to-morrow. Once again and in the most prominent and practical manner our KING and our QUEEN have displayed their known feeling towards the London hospitals, and so far-reaching is the influence of their opinion, because so genuine is the personal affection which they inspire, that we may hope that the total to be received this year by the Metropolitan Hospital Sunday Fund will be the one which has always been regarded as the proper figure for an annual collection in such a city and for such an object—viz., £100,000.

Following hard upon the invaluable assistance of their Majesties there was held this week at the Mansion House an important meeting with the object of furthering public interest in the hospitals and medical charities of the metropolis. At this meeting His Grace the ARCHBISHOP OF CANTERBURY brought forward a motion in these terms: "That in view of the great interest taken by HIS MAJESTY in promoting the welfare of the metropolitan hospitals this meeting pledges itself to use every effort to make the Hospital Sunday collection a 'record' one this year." The Archbishop said that the corporate life of which Londoners should be proud would be deliberately set on one side if the claims of the London hospitals for real, substantial, and permanent support were ignored—indeed, that those doing so would place themselves outside the pale of ordinary civilisation. That is the view—the strong, clear view—that we should have expected his Grace to take, and it is our own view. No citizen is worthy of the name of citizen who does not acknowledge cheerfully that it is his duty to help to the best of his ability the sick and suffering poor of the community. Sir R. DOUGLAS POWELL in seconding and Sir FREDERICK TREVES in supporting the motion, which was unanimously adopted, took practically the same line, though using different illustrations to point their words They showed that not only had the work done by the hospitals of London enormously increased in bulk but that by its higher scientific standards it was able to do incalculably more permanent good than was possible under older conditions. This is a side which is too often neglected by those who are speaking in behalf of hospital charity, but it was made very definitely by both the speakers who affirmed out of an enormous experience of hospitals that the public, in return for their contributions, received benefits which repaid the debt over and over again. Self-interest, in short, should also inspire the vast generosity that we hope to record as the result of the collections to-morrow in the various metropolitan places of worship. Have we not in these few words justified a belief that the record total will be reached?—indeed, we do not see why the ideal figure should be fixed at any sum. Love of GOD and love of man, loyalty to the Crown and loyalty to the ordinary standards of civilisation, generosity and prudence alike, should prevail with us to give to the limit of our power.

The Royal Dental Hospital and its Honorary Anæsthetists.

IT is satisfactory to learn that the affairs of the Royal *Dental Hospital as regards its staff of anæsthetists* are being settled in a manner that complies to some extent with the views that we expressed in these columns some four months ago, at a time when those responsible for the management of the hospital appeared to be on the eve of a most unfortunate departure. The Royal Dental Hospital would certainly have suffered not only in prestige but in its capacity for fulfilling the purposes of its existence had the committee of management persisted in its original proposal, which was virtually the summary dismissal of its honorary staff of anæsthetists. The proposal was made hastily and without proper regard either for the needs of the hospital or for the ordinary forms of courtesy, and if it had been carried out the charity would have suffered the obloquy of being placed in a retrograde position. Both the medical profession and the public at large would have seen in the failure to recognise the importance of maintaining a strong staff of anæsthetists a remarkable indifference to the trend of modern scientific opinion. The hospital authorities appear anxious now to escape this reproach. They are also desirous of avoiding the appearance of belittling the services of their staff of anæsthetists, an appearance that, considering the traditions of the hospital and how intimately the progress of our knowledge of anæsthetics in this country is bound up with the practice within its walls, was a peculiarly unfortunate one. If we are not able to say that the scheme of reform which it is proposed to adopt is a perfect one, we are glad to recognise a spirit of conciliation in the new plan for the regulation of the administration of anæsthetics in this important institution.

The committee of management of the Royal Dental Hospital has now adopted the report presented to it by the subcommittee appointed early in the year to consider and to report upon the arrangements for the administration of anæsthetics at the hospital. This report was carefully discussed at a meeting held on May 21st and may be considered to embody the views of the authorities. It commences by alluding to the constantly increasing number of patients requiring anæsthetics and to the difficulty in satisfactorily accomplishing the large number of extractions which have to be made. As the obvious way of dealing with the mass of work the appointment is recommended of two paid officers whose duty it shall be to see "that no case requiring an anæsthetic is dismissed without treatment." This is not a very clear definition of the functions of the paid anæsthetists. They will be engaged, we take it, in the administration of anæsthetics when these are required, not in arranging for the reception, or the dismissal, of patients, for which they should be in no way responsible. Where there is a doubt as to the propriety of administering anæsthetics the honorary anæsthetist rather than the paid officer would, we presume, be the authority relied upon for a decision. The next section of the report deals with the appointment of the honorary anæsthetists and of these it is recommended that six should be appointed "to have the general supervision of the department and to be responsible for its efficient management to the committee of management." This seems clear enough, but when the duties of the honorary anæsthetists are set out in detail it is not easy to understand how they will perform them. They are to be six in number and "each honorary anæsthetist is to attend *at the hospital one day in each week* (the respective days to be arranged amongst themselves), either morning or afternoon, for the purposes of administering anæsthetics, of giving advice and instruction to the house anæsthetists, and of generally supervising the department." If this paragraph means that each anæsthetist shall once a week spend a morning or else an afternoon at the hospital, then, as there are to be but six anæsthetists, obviously five mornings or afternoons remain unprovided for if, as we believe, the hospital is not open to patients on Saturday afternoons or during Sundays at any hour. It may be intended that each honorary anæsthetist shall spend one day a week at the hospital, that day being made up of two mornings, or of two afternoons, or of one morning and one afternoon, in which case one member of the honorary staff would get a weekly half-holiday. The paragraph that follows is equally puzzling, for it states that the anæsthetists shall "when requested, either by a dental surgeon, or in his absence by the dental superintendent, attend, on their own day as speedily as possible, to administer anæsthetics in special cases." But surely the honorary anæsthetists should not require special requests to attend on "their own day" when they would presumably be in the building.

We have said enough, and in no spirit of carping, to show that the wording of the adopted report is open to objection; to the matter of it we take little exception. The present honorary staff of anæsthetists will resign so as to allow of the remodelling of the department, but they will be eligible, *of course, for* re-election, though only six of them can retain their posts. The holding of the posts will be subject to annual re-election. We see no particular gain in the reduction of the number of honorary anæsthetists and it is highly important that the process of selection decided upon should not be allowed to look as though it had been meant to secure the absence of any particular member of the present staff. The immediate result of the reduction in the staff will be that on a certain number of mornings or afternoons the administration of anæsthetics may be entirely in the hands of the paid or house anæsthetists, and we do not know what grounds the committee of management may have for supposing that for these posts men of much experience will be available. This, however, remains to be seen and we hope heartily that an honest attempt to meet a very serious difficulty will result in success. But we would urge upon the committee of management the absolute necessity of revising the phraseology of the report before transforming it into new regulations. It will be courting a recurrence of trouble if the character and scope of the work expected from the honorary staff of anæsthetists and from the house anæsthetists are left in any sort of doubt. The committee of management should define exactly what are the duties which it requires, and having done so there will be nothing but praise for it if it takes the most drastic steps to insure those duties being performed.

The General Medical Council and the Royal Colleges of Physicians of London and Surgeons of England.

ON several occasions during the last few years it has been our duty to refer to the lamentable dispute which has arisen between the General Medical Council on the one part and the Royal College of Physicians of London and the Royal College of Surgeons of England on the other with regard to the conduct of the earlier portion of medical education—a dispute which has now reached a stage at which accommodation seems more difficult than ever and from which any advance on either side seems more likely to injure than to benefit the cause which both of the disputants, no doubt with entire sincerity, declare that they have at heart. It will be remembered that the Council several years ago, after prolonged deliberation and with the full assent of the representatives of the London Colleges, determined to increase the length of the medical curriculum from four years to five and to allow the first of these years to be devoted, mainly or entirely, to physics and biology. The change was very generally approved by the profession and after a necessary period of transition it was commonly believed to have been brought into operation and to be working satisfactorily to all concerned. From this belief the Council was somewhat rudely awakened by a communication from the Royal College of Surgeons in Ireland in which it was set forth that the new regulations had, in fact, been evaded by the London Colleges in the sense that they accepted as the first year of the new curriculum what was, in fact, the last year of ordinary school education conducted at almost any establishment in which instruction in physics and biology was said to form part of the course. The Irish College pointed out that its own strict observance of the recommendation of the Council placed it at a great disadvantage as compared with competing qualifying bodies which disregarded it and intimated that unless the Council could induce the London Colleges to conform the Irish College might be compelled to cease from doing so. It is needless to follow the details of a controversy every step of which has been recorded and commented upon in our columns. We need only say that the Council determined to refuse registration to so-called "medical" students who were still pupils at common schools unrecognised by the Council and that the London Colleges, in reply, ceased to require registration as a condition of examination for their diplomas. The Council appointed a strong committee, of which the representatives of the two London Colleges were members, to inquire into and to report upon the circumstances of the case, and this committee, the two representatives in question alone dissenting, recommended the Council to report to the Privy Council that the course of study required by the Colleges was, in the terms of the Medical Acts, "insufficient" to secure the possession of the necessary skill and knowledge for the practice of the profession. In the meanwhile the advice of counsel had been sought upon the legal aspects of the question, and finally it was carried as an amendment to the report of the committee that the examinations of the Conjoint Board in chemistry, physics, and biology should be visited and inspected by Dr. WINDLE and Professor CAMPBELL BROWN on behalf of the Council and that the whole matter should be suffered to rest until the report of this inspection had been received.

The report in question was presented to the Council during the session just concluded and its consideration was adjourned to a special session to be commenced on July 15th. We have already published the essential parts of the report, and it is sufficient now to say that it entirely supports the contention of those who maintain that the knowledge gained during the last year of school teaching is of no appreciable value as a preparation for medical study. "Nothing struck us more forcibly," say the visitor and inspector, "than the fact that scarcely a single candidate presented himself in biology who could be said to have exhibited the possession of any real grasp of the elementary principles of the subject." The ignorance of many of the candidates is said to have been "unfathomable" and the general character of the examination such that "a candidate might very well pass and does pass with only an empirical knowledge of a few facts crammed up from a book or a teacher and with no understanding of elementary principles." It is abundantly manifest that the first year of what is nominally medical study, as it has been conducted under the regulations of the London Colleges, has been of no practical value to the students, either as regards mental training or as regards the acquirement of knowledge calculated to afford a satisfactory foundation for future attainments. On the presentation of the report SIR VICTOR HORSLEY gave notice of his intention to move that the insufficiency of the courses of study and examination should be represented to the Privy Council in accordance with the terms of the Medical Acts; and this notice appeared in the *Times* report of the proceedings of the Council on the following day. The PRESIDENT called attention to it as having appeared by error, inasmuch as the notice had been withdrawn from the consideration of the Council for the time being. At any rate, it may be regarded as a declaration of war against the Colleges and if it should hereafter be adopted by the Council it can scarcely fail to be productive of very mischievous consequences.

The report of the visitor and inspector has, of course, been communicated to the two Colleges concerned and the College of Physicians has not yet furnished the Council with its commentary. That of the College of Surgeons has been received and published; and it would be difficult, we think, to conceive a document displaying a more complete incapacity to discern the magnitude and the character of the issues which are involved. An apparent and wholly unimportant verbal inconsistency between two sentences of the report is seized on; and "we"—i.e., the College—"are of opinion that the visitor and inspector are in error in supposing that the examination is not sufficient for the purpose for which it is intended. This purpose is the testing of such knowledge of chemistry, physics, and biology as a student may acquire in proper laboratories and under sound teachers in the first year of his medical studies." Such an attitude is manifestly hopeless and would clearly compel the Council to report to the Privy Council in the manner proposed by Sir VICTOR HORSLEY. Of the result there could, we think, be no doubt. The Colleges would support one another with the whole of their influence and the question of the sufficiency or insufficiency of the current system of medical education would be argued before an incompetent legal tribunal, certain to be unduly influenced by the supposed authority of venerable corporations. The effect produced upon the public would be to increase their distrust of medical science and to give a new lease to quackery and to "anti-ism." The licensing bodies, entirely released from their present doubtful allegiance to the Council, would be free to render themselves more and more acceptable to students and the standard of qualification would decline steadily under the influence of open competition. We hope it is not too late to appeal to the Royal College of Physicians of London to stay the downward course of events by an act of wise and conciliatory statesmanship, such as the history and repute of the College give us a right to expect from those who control its destinies. The exceeding badness of the education given at the "approved" schools has now been rendered manifest; and the College might gracefully take the lead in revising both the list and the requirements. Sir VICTOR HORSLEY'S motion will meet with no influential support unless the Colleges themselves render its acceptance inevitable, for doubtless the Council has no desire to provoke a contest which, however it terminated, could only be disastrous to all concerned. It is manifest that the Council cannot recede from its present position without absolute and irrecoverable loss of authority; and it is equally manifest that such a loss would reduce the granting of medical qualifications to a mere Dutch auction between competing bodies. From such an issue we appeal to the Royal College of Physicians of London to preserve both the profession and the country, and we feel confident that we shall not appeal in vain.

Annotations.

"Ne quid nimis."

THE BALLACHULISH CASE.
